Description

BACKGROUND OF THE INVENTION

5 The present invention relates to introduction of naked DNA and RNA sequences into a vertebrate to achieve controlled expression of a polypeptide. It is useful in gene therapy, vaccination, and any therapeutic situation in which a gene product such as a polypeptide should be administered to cells *in vivo*.

Current research in gene therapy has focused on "permanent" cures, in which DNA is integrated into the genome of the patient. Viral vectors are presently the most frequently used means for transforming the patient's cells and introducing DNA into the genome. In an indirect method, viral vectors, carrying new genetic information, are used to infect target cells removed from the body, and these cells are then re-implanted. Direct *in vivo* gene transfer into postnatal animals has been reported for formulations of DNA encapsulated in liposomes and DNA entrapped in proteoliposomes containing viral envelope receptor proteins (Nicolau et al., Proc. Natl. Acad. Sci. USA 80:1068-1072 (1983); Kaneda et al., Science 243:375-378 (1989); Mannino et al., Biotechniques 6:682-690 (1988)). Positive results have also been described with calcium phosphate coprecipitated DNA (Benvenisty and Reshef Proc. Natl. Acad. Sci. USA 83:9551-9555 (1986)).

The clinical application of gene therapy, as well as the utilization of recombinant retrovirus vectors, has been delayed because of safety considerations. Integration of exogenous DNA into the genome of a cell can cause DNA damage and possible genetic changes in the recipient cell that could predispose to malignancy. A method which avoids these potential problems would be of significant benefit in making gene therapy safe and effective.

Vaccination with immunogenic proteins has eliminated or reduced the incidence of many diseases; however there are major difficulties in using proteins associated with other pathogens and disease states as immunogens. Many protein antigens are not intrinsically immunogenic. More often, they are not effective as vaccines because of the manner in which the immune system operates.

25 The immune system of vertebrates consists of several interacting components. The best characterized and most important parts are the humoral and cellular (cytolytic) branches. Humoral immunity involves antibodies, proteins which are secreted into the body fluids and which directly recognize an antigen. The cellular system, in contrast, relies on special cells which recognize and kill other cells which are producing foreign antigens. This basic functional division reflects two different strategies of immune defense. Humoral immunity is mainly directed at antigens which are exogenous to the animal whereas the cellular system responds to antigens which are actively synthesized within the animal.

Antibody molecules, the effectors of humoral immunity, are secreted by special B lymphoid cells, B cells, in response to antigen. Antibodies can bind to and inactivate antigen directly (neutralizing antibodies) or activate other cells of the immune system to destroy the antigen.

Cellular immune recognition is mediated by a special class of lymphoid cells, the cytotoxic T cells. These cells do not recognize whole antigens but instead they respond to degraded peptide fragments thereof which appear on the surface of the target cell bound to proteins called class I major histocompatibility complex (MHC) molecules. Essentially all nucleated cells have class I molecules. It is believed that proteins produced within the cell are continually degraded to peptides as part of normal cellular metabolism. These fragments are bound to the MHC molecules and are transported to the cell surface. Thus the cellular immune system is constantly monitoring the spectrum of proteins produced in all cells in the body and is poised to eliminate any cells producing foreign antigens.

Vaccination is the process of preparing an animal to respond to an antigen. Vaccination is more complex than immune recognition and involves not only B cells and cytotoxic T cells but other types of lymphoid cells as well. During vaccination, cells which recognize the antigen (B cells or cytotoxic T cells) are clonally expanded. In addition, the population of ancillary cells (helper T cells) specific for the antigen also increase. Vaccination also involves specialized antigen presenting cells which can process the antigen and display it in a form which can stimulate one of the two pathways.

Vaccination has changed little since the time of Louis Pasteur. A foreign antigen is introduced into an animal where it activates specific B cells by binding to surface immunoglobulins. It is also taken up by antigen processing cells, wherein it is degraded, and appears in fragments on the surface of these cells bound to Class II MHC molecules. Peptides bound to class II molecules are capable of stimulating the helper class of T cells. Both helper T cells and activated B cells are required to produce active humoral immunization. Cellular immunity is thought to be stimulated by a similar but poorly understood mechanism.

Thus two different and distinct pathways of antigen processing produce exogenous antigens bound to class II MHC molecules where they can stimulate T helper cells, as well as endogenous proteins degraded and bound to class I MHC molecules and recognized by the cytotoxic class of T cells.

55 There is little or no difference in the distribution of MHC molecules. Essentially all nucleated cells express class I molecules whereas class II MHC proteins are restricted to some few types of lymphoid cells.

Normal vaccination schemes will always produce a humoral immune response. They may also provide cytotoxic immunity. The humoral system protects a vaccinated individual from subsequent challenge from a pathogen and can

prevent the spread of an intracellular infection if the pathogen goes through an extracellular phase during its life cycle; however, it can do relatively little to eliminate intracellular pathogens. Cytotoxic immunity complements the humoral system by eliminating the infected cells. Thus effective vaccination should activate both types of immunity.

A cytotoxic T cell response is necessary to remove intracellular pathogens such as viruses as well as malignant cells. It has proven difficult to present an exogenously administered antigen in adequate concentrations in conjunction with Class I molecules to assure an adequate response. This has severely hindered the development of vaccines against tumor-specific antigens (e.g., on breast or colon cancer cells), and against weakly immunogenic viral proteins (e.g., HIV, Herpes, non-A, non-B hepatitis, CMV and EBV).

It would be desirable to provide a cellular immune response alone in immunizing against agents such as viruses for which antibodies have been shown to enhance infectivity. It would also be useful to provide such a response against both chronic and latent viral infections and against malignant cells.

The use of synthetic peptide vaccines does not solve these problems because either the peptides do not readily associate with histocompatibility molecules, have a short serum half-life, are rapidly proteolyzed, or do not specifically localize to antigen-presenting monocytes and macrophages. At best, all exogenously administered antigens must compete with the universe of self-proteins for binding to antigen-presenting macrophages.

Major efforts have been mounted to elicit immune responses to poorly immunogenic viral proteins from the herpes viruses, non-A, non-B hepatitis, HIV, and the like. These pathogens are difficult and hazardous to propagate *in vitro*. As mentioned above, synthetic peptide vaccines corresponding to viral-encoded proteins have been made, but have severe pitfalls. Attempts have also been made to use vaccinia virus vectors to express proteins from other viruses. However, the results have been disappointing, since (a) recombinant vaccinia viruses may be rapidly eliminated from the circulation in already immune individuals, and (b) the administration of complex viral antigens may induce a phenomenon known as "antigenic competition," in which weakly immunogenic portions of the virus fail to elicit an immune response because they are out-competed by other more potent regions of the administered antigen.

Another major problem with protein or peptide vaccines is anaphylactic reaction which can occur when injections of antigen are repeated in efforts to produce a potent immune response. In this phenomenon, IgE antibodies formed in response to the antigen cause severe and sometimes fatal allergic reactions.

Accordingly, there is a need for a method for invoking a safe and effective immune response to this type of polypeptide. Moreover, there is a great need for a method that will associate these antigens with Class I histocompatibility antigens on the cell surface to elicit a cytotoxic T cell response, avoid anaphylaxis and proteolysis of the material in the serum, and facilitate localization of the material to monocytes and macrophages.

A large number of disease states can benefit from the administration of therapeutic polypeptides. Such polypeptides include lymphokines, such as interleukin-2, tumor necrosis factor, and the interferons; growth factors, such as nerve growth factor, epidermal growth factor, and human growth hormone; tissue plasminogen activator; factor VIII:C; granulocyte-macrophage colony-stimulating factor; erythropoietin; insulin; calcitonin; thymidine kinase; and the like. Moreover, selective delivery of toxic polypeptides (such as ricin, diphtheria toxin, or cobra venom factor) to diseased or neoplastic cells can have major therapeutic benefits. Current polypeptide delivery systems suffer from significant problems, including the inability to effectively incorporate functional cell surface receptors onto cell membranes, and the necessity of systemically administering large quantities of the polypeptide (with resultant undesirable systemic side effects) in order to deliver a therapeutic amount of the polypeptide into or onto the target cell.

These above-described problems associated with gene therapy, immunization, and delivery of therapeutic polypeptides to cells are addressed by the present invention.

DESCRIPTION OF THE DRAWINGS

Figure 1 comprises autoradiograms of chromatographic studies showing the expression of the CAT gene in mouse muscle.

Figure 2 comprises photomicrographs of muscle tissue stained for beta-galactosidase activity following injection with the pRSVLac-Z DNA vector.

Figure 3 presents data for luciferase activity in muscle following the injection of β gLuc β gA_n into muscle.

Figure 4 presents an autoradiogram of a Southern blot after analysis of extracts from pRSVL-injected muscle.

Figure 5 comprises graphs showing antibody production in mice following the injection of a gene for an immunogenic polypeptide.

Figure 6 comprises graphs showing antibody production in mice following the injection of mouse cells transfected with a gene for an immunogenic polypeptide.

SUMMARY OF THE INVENTION

In a first aspect the present invention provides use of a naked polynucleotide, defined as being free from associa-

tion with transfection-facilitating viral particles, liposomal formulations, charged lipids, and precipitating agents, and further defined as being non-integrating into genomes of said cells, with the proviso that the naked polynucleotide is not an infectious viral polynucleotide, or an antisense polynucleotide and is not in association with transfection facilitating proteins; in the preparation of a medicament; said naked polynucleotide when introduced *in vivo* directly into tissue of
 5 said vertebrate operatively encodes a gene product that is therapeutic or immunogenic when produced as an expression product in cells of said vertebrate and that exerts a desired therapeutic or immunogenic effect *in vivo*. In a second aspect there is provided a naked polynucleotide, defined as being free from association with transfection-facilitating viral particles, liposomal formulations, charged lipids, and precipitating agents, and further defined as being non-integrating into genomes of said cells; with the proviso that the naked polynucleotide is not an infectious viral polynucleotide, or an antisense polynucleotide and is not in association with transfection facilitating proteins; which operatively
 10 encodes a gene product that is therapeutic or immunogenic when produced as an expression product and that exerts a desired therapeutic or immunogenic effect after introduction into vertebrate tissue *in vivo*, for use as a medicament *in vivo*. Generally speaking, the present invention allows for delivering a pharmaceutical or immunogenic polypeptide to the interior of a cell of a vertebrate *in vivo*, comprising the step of introducing a preparation comprising a pharmaceutically acceptable injectable carrier and a naked polynucleotide operatively coding for the polypeptide into the interstitial space of a tissue comprising the cell, whereby the naked polynucleotide is taken up into the interior of the cell and has an immunogenic or pharmacological effect on the vertebrate. The present invention also allows for introducing a naked polynucleotide into muscle cells *in vivo*, comprising the steps of providing a composition comprising a naked polynucleotide in a pharmaceutically acceptable carrier, and contacting the composition with muscle tissue of a vertebrate *in vivo*, whereby the naked polynucleotide is introduced into muscle cells of the tissue. The naked polynucleotide may code for a therapeutic polypeptide that is expressed by the muscle cells after the contacting step to provide therapy to the vertebrate. Similarly, it may code for an immunogenic polypeptide that is expressed by the muscle cells after the contacting step and which generates an immune response, thereby immunizing the vertebrate.

One particularly attractive aspect is that the invention may provide for obtaining long term administration of a polypeptide to a vertebrate, comprising the step of introducing a naked DNA sequence operatively coding for the polypeptide interstitially into tissue of the vertebrate, whereby cells of the tissue produce the polypeptide for at least one month or at least 3 months, more preferably at least 6 months. In this embodiment of the invention, the cells producing the polypeptide are nonproliferating cells, such as muscle cells.

Another use according to the invention is a use of a naked polynucleotide for obtaining transitory expression of a polypeptide in a vertebrate, comprising the step of introducing a naked mRNA sequence operatively coding for the polypeptide interstitially into tissue of the vertebrate, whereby cells of the tissue produce the polypeptide for less than about 20 days, usually less than about 10 days, and often less than 3 or 5 days. For many of the uses of the invention, administration into solid tissue is preferred.

One important aspect of the invention is a use for treatment of muscular dystrophy, comprising the steps of introducing a therapeutic amount of a composition comprising a naked polynucleotide operatively coding for dystrophin in a pharmaceutically acceptable injectable carrier *in vivo* into muscle tissue of an animal suffering from muscular dystrophy, whereby the polynucleotide is taken up into the cells and dystrophin is produced *in vivo*. Preferably, the composition is introduced interstitially into the muscle tissue.

Typically, the present invention may also include pharmaceutical products for all of the uses contemplated as described herein. For example, there may generally be provided a pharmaceutical product, comprising naked polynucleotide, operatively coding for a gene product such as a biologically active polypeptide, in physiologically acceptable administrable form, in a container, and a notice associated with the container in form prescribed by a governmental agency regulating the manufacture, use, or sale of pharmaceuticals, which notice is reflective of approval by the agency of the form of the polynucleotide for human or veterinary administration. Such notice, for example, may be the labeling approved by the U.S. Food and Drug Administration or other regulatory body for prescription drugs, or the approved product insert.

In another embodiment, the invention may also provide a pharmaceutical product, comprising naked polynucleotide, operatively coding for a biologically active polypeptide, in solution in a physiologically acceptable injectable carrier and suitable for introduction interstitially into a tissue to cause cells of the tissue to express the polypeptide, a container enclosing the solution, and a notice associated with the container in form prescribed by a governmental or regulatory agency regulating the manufacture, use, or sale of pharmaceuticals, which notice is reflective of approval by the agency of manufacture, use, or sale of the solution of polynucleotide for human or veterinary administration. The polypeptide may be immunogenic and administration of the solution to a human may serve to vaccinate the human, or an animal. Similarly, the polypeptide may be therapeutic and administration of the solution to a vertebrate in need of therapy relating to the polypeptide will have a therapeutic effect.

One particularly important use of the invention relates to the preparation of a pharmaceutical product for use in treatment of muscular dystrophy, comprising a sterile, pharmaceutically acceptable carrier, a pharmaceutically effective amount of a naked polynucleotide operatively coding for dystrophin in the carrier, and a container enclosing the carrier

and the polynucleotide in sterile fashion. Preferably, the polynucleotide is DNA.

From yet another perspective, the invention includes the preparation of a pharmaceutical product for use in supplying a biologically active polypeptide to a vertebrate, comprising a pharmaceutically effective amount of a naked polynucleotide operatively coding for the polypeptide, a container enclosing the carrier and the polynucleotide in a sterile fashion, and means associated with the container for permitting transfer of the polynucleotide from the container to the interstitial space of a tissue, whereby cells of the tissue can take up and express the polynucleotide. The means for permitting such transfer can include a conventional septum that can be penetrated, e.g., by a needle. Alternatively, when the container is a syringe, the means may be considered to comprise the plunger of the syringe or a needle attached to the syringe. Containers used in association with the present invention will usually have at least 1, preferably at least 5 or 10, and more preferably at least 50 or 100 micrograms of naked polynucleotide, to provide one or more unit dosages. For many applications, the container will have at least 500 micrograms or 1 milligram, and often will contain at least 50 or 100 milligrams of naked polynucleotide.

Another use of the invention is the preparation of a pharmaceutical product for use in immunizing a vertebrate, comprising a pharmaceutically effective amount of a naked polynucleotide operatively coding for an immunogenic polypeptide, a sealed container enclosing the polynucleotide in a sterile fashion, and means associated with the container for permitting transfer of the polynucleotide from the container to the interstitial space of a tissue, whereby cells of the tissue can take up and express the polynucleotide.

Still another aspect of the present invention is the use of naked polynucleotide operatively coding for a physiologically active polypeptide in the preparation of a pharmaceutical for introduction interstitially into tissue to cause cells comprising the tissue to produce the polypeptide. The pharmaceutical, for example, may be for introduction into muscle tissue whereby muscle cells produce the polypeptide. Also contemplated is such use, wherein the polypeptide is dystrophin and the pharmaceutical is for treatment of muscular dystrophy.

The tissue into which the naked polynucleotide is introduced can be a persistent, non-dividing cell. The naked polynucleotide may be either a DNA or RNA sequence. When the naked polynucleotide is DNA, it can also be a DNA sequence which is itself non-replicating, but is inserted into a plasmid, and the plasmid further comprises a replicator. The DNA is a sequence engineered so as not to integrate into the host cell genome. The naked polynucleotide sequences may code for a polypeptide which is either contained within the cells or secreted therefrom, or may comprise a sequence which directs the secretion of the polypeptide.

The DNA sequence may also include a promoter sequence. In one preferred embodiment, the DNA sequence includes a cell-specific promoter that permits substantial transcription of the DNA only in predetermined cells. The DNA may also code for a polymerase for transcribing the DNA, and may comprise recognition sites for the polymerase and the injectable preparation may include an initial quantity of the polymerase.

In many instances, it is preferred that the naked polynucleotide is translated for a limited period of time so that the polypeptide delivery is transitory. The polypeptide may be a therapeutic polypeptide, and may comprise an enzyme, a hormone, a lymphokine, a receptor, particularly a cell surface receptor, a regulatory polypeptide, such as a growth factor or other regulatory agent, or any other polypeptide that one desires to deliver to a cell in a living vertebrate and for which corresponding DNA or mRNA can be obtained.

In preferred embodiments, the naked polynucleotide is introduced into muscle tissue; in other embodiments the naked polynucleotide is incorporated into tissues of skin, brain, lung, liver, spleen or blood. The preparation is injected into the vertebrate by a variety of routes, which may be intradermally, subdermally, intrathecally, or intravenously, or it may be placed within cavities of the body. In a preferred embodiment, the naked polynucleotide is injected intramuscularly. In still other embodiments, the preparation comprising the naked polynucleotide is impressed into the skin. Transdermal administration is also contemplated, as is inhalation.

In one preferred embodiment, the naked polynucleotide is DNA coding for both a polypeptide and a polymerase for transcribing the DNA, and the DNA includes recognition sites for the polymerase and the injectable preparation further includes a means for providing an initial quantity of the polymerase in the cell. The initial quantity of polymerase may be physically present together with the DNA. Alternatively, it may be provided by including mRNA coding therefor, which mRNA is translated by the cell. In this embodiment of the invention, the DNA is preferably a plasmid. Preferably, the polymerase is phage T7 polymerase and the recognition site is a T7 origin of replication sequence.

In accordance with another aspect of the invention, there is provided a use of a naked polynucleotide in the preparation of a medicament for treating a disease associated with the deficiency or absence of a specific polypeptide in a vertebrate, comprising the steps of obtaining an injectable preparation comprising a pharmaceutically acceptable injectable carrier containing a naked polynucleotide coding for the specific polypeptide; introducing the injectable preparation into a vertebrate and permitting the polynucleotide to be incorporated into a cell, wherein the polypeptide is formed as the translation product of the polynucleotide, and whereby the deficiency or absence of the polypeptide is compensated for. In preferred embodiments, the preparation is introduced into muscle tissue and the medicament is applied repetitively. The use is advantageously applied where the deficiency or absence is due to a genetic defect. The naked polynucleotide is preferably a non-replicating DNA sequence; the DNA sequence may also be incorporated into a plasmid

vector which comprises an origin of replication.

In one of the preferred embodiments, the naked polynucleotide codes for a non-secreted polypeptide, and the polypeptide remains *in situ*. According to this embodiment, when the naked polynucleotide codes for the polypeptide dystrophin, the use provides a medicament for treating Duchenne's syndrome; alternatively, when the naked polynucleotide codes for the polypeptide phenylalanine hydroxylase, the use provides a medicament for treating phenylketonuria. In another preferred embodiment of the method, the naked polynucleotide codes for a polypeptide which is secreted by the cell and released into the circulation of the vertebrate; in a particularly preferred embodiment the naked polynucleotide codes for human growth hormone.

In yet another embodiment, there is provided use of a naked polynucleotide in the preparation of a medicament for treating hypercholesterolemia wherein a naked polynucleotide coding for a receptor associated with cholesterol homeostasis is introduced into a liver cell, and the receptor is expressed by the cell.

In accordance with another aspect of the present invention, there is provided use of a naked polynucleotide in the preparation of a medicament for immunizing a vertebrate, comprising the steps of obtaining a preparation comprising an expressible naked polynucleotide coding for an immunogenic translation product, and introducing the preparation into a vertebrate wherein the translation product of the polynucleotide is formed by a cell of the vertebrate, which elicits an immune response against the immunogen. In one embodiment, an injectable preparation comprises a pharmaceutically acceptable carrier containing an expressible naked polynucleotide coding for an immunogenic polypeptide, and on the introduction of the preparation into the vertebrate, the polynucleotide is incorporated into a cell of the vertebrate wherein an immunogenic translation product of the polynucleotide is formed, which elicits an immune response against the immunogen.

In any of the embodiments of the invention, the immunogenic product may be secreted by the cells, or it may be presented by a cell of the vertebrate in the context of the major histocompatibility antigens, thereby eliciting an immune response against the immunogen. The uses may be practiced using non-dividing, differentiated cells from the vertebrates, which cells may be lymphocytes; alternatively, it may be practiced using partially differentiated skin fibroblasts which are capable of dividing. In a preferred embodiment, the use is practiced by incorporating the naked polynucleotide coding for an immunogenic translation product into muscle tissue.

The naked polynucleotide used for immunization is preferably an mRNA sequence, although a non-replicating DNA sequence may be used. The naked polynucleotide may be introduced into tissues of the body using an injectable carrier.

The carrier preferably is isotonic, hypotonic, or weakly hypertonic, and has a relatively low ionic strength, such as provided by a sucrose solution. The medicament may further advantageously comprise a source of a cytokine which is incorporated in the form of a polypeptide or as a naked polynucleotide.

The medicament may be used to selectively elicit a humoral immune response, a cellular immune response, or a mixture of these. In embodiments wherein the cell expresses major histocompatibility complex of Class I, and the immunogenic polypeptide is presented in the context of the Class I complex, the immune response is cellular and comprises the production of cytotoxic T-cells.

In one such embodiment, the immunogenic polypeptide is associated with a virus, is presented in the context of Class I antigens, and stimulates cytotoxic T-cells which are capable of destroying cells infected with the virus. A cytotoxic T-cell response may also be produced according to the use where the naked polynucleotide codes for a truncated viral antigen lacking humoral epitopes.

In another of these embodiments, the immunogenic polypeptide is associated with a tumor, is presented in the context of Class I antigens, and stimulates cytotoxic T cells which are capable of destroying tumor cells. In yet another embodiment, the cells may express major histocompatibility antigen of class I and class II, and the immune response is both humoral and cellular and comprises the production of both antibody and cytotoxic T-cells.

In another embodiment, there is provided use of a naked polynucleotide in the preparation of a medicament for immunizing a vertebrate, comprising the steps of obtaining an expressible naked polynucleotide coding for an immunogenic polypeptide, and introducing the polynucleotide in an injectable carrier into a vertebrate, whereby the polynucleotide is incorporated into a monocyte, a macrophage, or another cell, where an immunogenic translation product of the polynucleotide is formed, and the product is processed and presented by the cell in the context of the major histocompatibility complex, thereby eliciting an immune response against the immunogen. Again, the naked polynucleotide is preferably mRNA, although DNA may also be used.

The present invention also encompasses the use of DNA coding for a polypeptide and for a polymerase for transcribing the DNA, and wherein the DNA includes recognition sites for the polymerase. The initial quantity of polymerase is provided by including mRNA coding therefor in the medicament, which mRNA is translated by the cell. The mRNA preferably is provided with means for retarding its degradation in the cell. This can include capping the mRNA, circularizing the mRNA, or chemically blocking the 5' end of the mRNA. The DNA used in the invention may be in the form of linear DNA or may be a plasmid. Episomal DNA is also contemplated. One preferred polymerase is phage T7 RNA polymerase and a preferred recognition site is a T7 RNA polymerase promoter.

DETAILED DESCRIPTION OF THE INVENTION

The practice of the present invention requires obtaining naked polynucleotide operatively coding for a gene product such as a polypeptide for incorporation into vertebrate cells. A polynucleotide operatively codes for a polypeptide when it has all the genetic information necessary for expression by a target cell, such as promoters and the like. These naked polynucleotides can be administered to the vertebrate by any method that delivers injectable materials to cells of the vertebrate, such as by injection into the interstitial space of tissues such as muscles or skin, introduction into the circulation or into body cavities or by inhalation or insufflation. A naked polynucleotide is injected or otherwise delivered to the animal with a pharmaceutically acceptable liquid carrier. For all applications, the liquid carrier is aqueous or partly aqueous, comprising sterile, pyrogen-free water. The pH of the preparation is suitably adjusted and buffered.

A number of the Examples make reference to the use of liposomes for transfection and transfections carried out *in vitro* for subsequent transplantation. It is to be appreciated that this is merely for comparative purposes and the use of liposomes for transfection and transfections carried out *in vitro* for subsequent transplantation is not encompassed by the present invention.

Naked Polynucleotide Materials

The naked polynucleotide materials used according to the methods of the invention comprise DNA and RNA sequences or DNA and RNA sequences coding for gene products such as polypeptides that have useful therapeutic or immunogenic applications. These polynucleotide sequences are naked in the sense that they are generally free from any delivery vehicle that can act to facilitate entry into the cell. In particular, the naked polynucleotide sequences are free of viral sequences, particularly any viral particles which may carry genetic information. They are similarly free from, or naked with respect to, any material which is previously acknowledged to promote transfection, such as liposomal formulations, charged lipids such as Lipofectin™ or precipitating agents such as CaPO₄.

The DNA sequences do not integrate into the genome of the host cell. These may be non-replicating DNA sequences, or specific replicating sequences genetically engineered to lack the genome-integration ability.

The naked polynucleotide sequences of the invention are DNA or RNA sequences having a therapeutic or immunogenic effect after being taken up by a cell. Examples of naked polynucleotides are DNA coding for an anti-sense RNA; or DNA coding for tRNA or rRNA to replace defective or deficient endogenous molecules. The naked polynucleotides of the invention can also code for therapeutic polypeptides. A polypeptide is understood to be any translation product of a polynucleotide regardless of size, and whether glycosylated or not, and includes peptides and proteins. Therapeutic polypeptides include as a primary example, those polypeptides that can compensate for defective or deficient species in an animal, or those that act through toxic effects to limit or remove harmful cells from the body.

Therapeutic naked polynucleotides provided by way of the invention can also code for immunity-conferring polypeptides, which can act as endogenous immunogens to provoke a humoral or cellular response, or both. The naked polynucleotides employed according to the present invention can also code for an antibody. In this regard, the term "antibody" encompasses whole immunoglobulin of any class, chimeric antibodies and hybrid antibodies with dual or multiple antigen or epitope specificities, and fragments, such as F(ab)₂, Fab', Fab and the like, including hybrid fragments. Also included within the meaning of "antibody" are conjugates of such fragments, and so-called antigen binding proteins (single chain antibodies) as described, for example, in U.S. Patent No. 4,704,692.

Thus, an isolated naked polynucleotide coding for variable regions of an antibody can be introduced, in accordance with the present invention, to enable a subject to produce antibody *in situ*. For illustrative methodology relating to obtaining antibody-encoding polynucleotides, see Ward et al. Nature, 341:544-546 (1989); Gillies et al., Biotechnol. 7:799-804 (1989); and Nakatani et al., *loc. cit.*, 805-810 (1989). The antibody in turn would exert a therapeutic effect, for example, by binding a surface antigen associated with a pathogen. Alternatively, the encoded antibodies can be anti-idiotypic antibodies (antibodies that bind other antibodies) as described, for example, in U.S. Patent No. 4,699,880. Such anti-idiotypic antibodies could bind endogenous or foreign antibodies in an individual, thereby to ameliorate or prevent pathological conditions associated with an immune response, e.g., in the context of an autoimmune disease.

Naked polynucleotide sequences of the invention preferably code for therapeutic or immunogenic polypeptides, and these sequences may be used in association with other naked polynucleotide sequences coding for regulatory polypeptides that control the expression of these polypeptides. The regulatory polypeptide can act by binding to genomic DNA so as to regulate its transcription; alternatively, it can act by binding to messenger RNA to increase or decrease its stability or translation efficiency.

The naked polynucleotide material delivered to the cells *in vivo* can take any number of forms, and the present invention is not limited to any particular polynucleotide coding for any particular polypeptide or group of polypeptides. It may contain only a fragment of a gene, or may code for multiple polypeptide sequences, and may additionally contain recognition and promoter sequences. Plasmids containing genes coding for a large number of physiologically active polypeptides and antigens or immunogens have been reported in the literature and can be readily obtained by those of

skill in the art.

Where the naked polynucleotide is to be DNA, promoters suitable for use in various vertebrate systems are well known. For example, for use in murine systems, suitable strong promoters include RSV LTR, MPSV LTR, SV40 IEP, and metallothionein promoter. In humans, on the other hand, promoters such as CMV IEP may advantageously be used. All forms of DNA, whether replicating or non-replicating, which do not become integrated into the genome, and which are expressible, are within the uses contemplated by the invention.

With the availability of automated nucleic acid synthesis equipment, both DNA and RNA can be synthesized directly when the nucleotide sequence is known or by a combination of PCR cloning and fermentation. Moreover, when the sequence of the desired polypeptide is known, a suitable coding sequence for the polynucleotide can be inferred.

When the naked polynucleotide is mRNA, it can be readily prepared from the corresponding DNA *in vitro*. For example, conventional techniques utilize phage RNA polymerases SP6, T3, or T7 to prepare mRNA from DNA templates in the presence of the individual ribonucleoside triphosphates. An appropriate phage promoter, such as a T7 origin of replication site is placed in the template DNA immediately upstream of the gene to be transcribed. Systems utilizing T7 in this manner are well known, and are described in the literature, e.g., in **Current Protocols In Molecular Biology**, §3.8 (Vol.1 1988).

One particularly preferred method for obtaining the mRNA used in the present invention is set forth in Examples 2-5. In general, however, it should be apparent that the pXGB plasmid or any similar plasmid that can be readily constructed by those of ordinary skill in the art can be used with a virtually unlimited number of cDNAs in practicing the present invention. Such plasmids may advantageously comprise a promoter for a desired RNA polymerase, followed by a 5' untranslated region, a 3' untranslated region, and a template for a poly A tract. There should be a unique restriction site between these 5' and 3' regions to facilitate the insertion of any desired cDNA into the plasmid. Then, after cloning the plasmid containing the desired gene, the plasmid is linearized by cutting in the polyadenylation region and is transcribed *in vitro* to form mRNA transcripts. These transcripts are preferably provided with a 5' cap, as demonstrated in Example 5. Alternatively, a 5' untranslated sequence such as EMC can be used which does not require a 5' cap.

While the foregoing represents a preferred method for preparing the mRNA, it will be apparent to those of skill in the art that many alternative methods also exist. For example, the mRNA can be prepared in commercially-available nucleotide synthesis apparatus. Alternatively, mRNA in circular form can be prepared. Exonuclease-resistant RNAs such as circular mRNA, chemically blocked mRNA, and mRNA with a 5' cap are preferred, because of their greater half-life *in vivo*.

In particular, one preferred mRNA is a self-circularizing mRNA having the gene of interest preceded by the 5' untranslated region of polio virus. It has been demonstrated that circular mRNA has an extremely long half-life (Harland & Misher, **Development** 102: 837-852 (1988)) and that the polio virus 5' untranslated region can promote translation of mRNA without the usual 5' cap (Pelletier & Sonnenberg, **Nature** 334:320-325 (1988)).

This material may be prepared from a DNA template that is self-splicing and generates circular "lariat" mRNAs, using the method of Been & Cech, **Cell** 47:206-216 (1986). We modify that template by including the 5' untranslated region of the polio virus immediately upstream of the gene of interest, following the procedure of Maniatis, T. et al. **MOLECULAR CLONING: A LABORATORY MANUAL**, Cold Spring Harbor, New York (1982).

In addition, the present invention includes the use of mRNA that is chemically blocked at the 5' and/or 3' end to prevent access by RNase. (This enzyme is an exonuclease and therefore does not cleave RNA in the middle of the chain.) Such chemical blockage can substantially lengthen the half life of the RNA *in vivo*. Two agents which may be used to modify RNA are available from Clontech Laboratories, Inc., Palo Alto, California: C2 AminoModifier (Catalog # 5204-1) and Amino-7-dUTP (Catalog # K1022-1). These materials add reactive groups to the RNA. After introduction of either of these agents onto an RNA molecule of interest, an appropriate reactive substituent can be linked to the RNA according to the manufacturer's instructions. By adding a group with sufficient bulk, access to the chemically modified RNA by RNase can be prevented.

Transient Gene Therapy

Unlike gene therapies proposed in the past, one major advantage of the present invention is the transitory nature of the polynucleotide synthesis in the cells. (We refer to this as reversible gene therapy, or TGT.) With naked mRNA introduced according to the present invention, the effect will generally last about one day. Also, in marked contrast to gene therapies proposed in the past, mRNA does not have to penetrate the nucleus to direct polypeptide synthesis; therefore, it should have no genetic liability.

In some situations, however, a more prolonged effect may be desired without incorporation of the exogenous polynucleic acid into the genome of the host organism. In order to provide such an effect, a preferred embodiment of the invention provides introducing a naked DNA sequence coding for a specific polypeptide into the cell. We have found, according to the uses of the invention, that non-replicating DNA sequences can be introduced into cells to provide production of the desired polypeptide for periods of about up to six months, and we have observed no evidence of integra-

tion of the DNA sequences into the genome of the cells. Alternatively, an even more prolonged effect can be achieved by introducing the DNA sequence into the cell by means of a vector plasmid having the DNA sequence inserted therein. Preferably, the plasmid further comprises a replicator. Such plasmids are well known to those skilled in the art, for example, plasmid pBR322, with replicator pMB1, or plasmid pMK16, with replicator ColE1 (Ausubel, Current Protocols in Molecular Biology, John Wiley and Sons, New York (1988) §II:1.5.2).

Results of studies of the time course of expression of DNA and mRNA introduced into muscle cells as described in Examples 1 and 13 indicate that mRNA expression is more rapid, although shorter in duration than DNA expression. An immediate and long lived gene expression can be achieved by administering to the cell an injectable preparation comprising both DNA and an RNA polymerase, such as the phage polymerases T7, T3, and SP6. The preparation also includes an initial source of the appropriate RNA polymerase, by either including the actual enzyme itself, or alternatively, an mRNA coding for that enzyme. When the preparation is introduced into the organism, it delivers the DNA and the initial source of RNA polymerase to the cell. The RNA polymerase, recognizing the promoters on the introduced DNA, transcribes both genes, resulting in translation products comprising more RNA polymerase and the desired polypeptide. Production of these materials continues until the introduced DNA (which is usually in the form of a plasmid) is degraded. In this manner, production of the desired polypeptide *in vivo* can be achieved in a few hours and be extended for one month or more.

Although not limited to the treatment of genetic disease, the uses of the invention can accordingly be appropriately applied to treatment strategies requiring delivery and functional expression of missing or defective genes.

The naked polynucleotides may be delivered to the interstitial space of tissues of the animal body, including those of muscle, skin, brain, lung, liver, spleen, bone marrow, thymus, heart, lymph, blood, bone, cartilage, pancreas, kidney, gall bladder, stomach, intestine, testis, ovary, uterus, rectum, nervous system, eye, gland, and connective tissue. Interstitial space of the tissues comprises the intercellular, fluid, mucopolysaccharide matrix among the reticular fibers of organ tissues, elastic fibers in the walls of vessels or chambers, collagen fibers of fibrous tissues, or that same matrix within connective tissue ensheathing muscle cells or in the lacunae of bone. It is similarly the space occupied by the plasma of the circulation and the lymph fluid of the lymphatic channels. Delivery to the interstitial space of muscle tissue is preferred for the reasons discussed below. They may be conveniently delivered by injection into the tissues comprising these cells. They are preferably delivered to and expressed in persistent, non-dividing cells which are differentiated, although delivery and expression may be achieved in non-differentiated or less completely differentiated cells, such as, for example, stem cells of blood or skin fibroblasts. We have discovered that *in vivo* muscle cells are particularly competent in their ability to take up and express naked polynucleotides. This ability may be due to the singular tissue architecture of muscle, comprising multinucleated cells, sarcoplasmic reticulum, and transverse tubular system. Naked polynucleotides may enter the muscle through the transverse tubular system, which contains extracellular fluid and extends deep into the muscle cell. It is also possible that the naked polynucleotides enter damaged muscle cells which then recover.

Muscle is also advantageously used as a site for the delivery and expression of naked polynucleotides in a number of therapeutic applications because animals have a proportionately large muscle mass which is conveniently accessed by direct injection through the skin; for this reason, a comparatively large dose of polynucleotides can be deposited in muscle by multiple injections, and repetitive injections, to extend therapy over long periods of time, are easily performed and can be carried out safely and without special skill or devices.

Muscle tissue can be used as a site for injection and expression of naked polynucleotides in a set of general strategies, which are exemplary and not exhaustive. First, muscle disorders related to defective or absent gene products can be treated by introducing naked polynucleotides coding for a non-secreted gene product into the diseased muscle tissue. In a second strategy, disorders of other organs or tissues due to the absence of a gene product, and which results in the build-up of a circulating toxic metabolite can be treated by introducing the specific therapeutic polypeptide into muscle tissue where the non-secreted gene product is expressed and clears the circulating metabolite. In a third strategy, a naked polynucleotide coding for a secretable therapeutic polypeptide can be injected into muscle tissue from where the polypeptide is released into the circulation to seek a metabolic target. This use is demonstrated in the expression of growth hormone gene injected into muscle, Example 18. Certain DNA segments, are known to serve as "signals" to direct secretion (Wickner, W.T. and H.F. Lodish, Science 230:400-407 (1985)), and these may be advantageously employed. Finally, in immunization strategies, muscle cells may be injected with naked polynucleotides coding for immunogenic polypeptides, and these polypeptides will be presented by muscle cells in the context of antigens of the major histocompatibility complex to provoke a selected immune response against the immunogen.

Tissues other than those of muscle, and having a less efficient uptake and expression of injected naked polynucleotides, may nonetheless be advantageously used as injection sites to produce therapeutic polypeptides or polynucleotides under certain conditions. One such condition is the use of a naked polynucleotide to provide a polypeptide which to be effective must be present in association with cells of a specific type; for example, the cell surface receptors of liver cells associated with cholesterol homeostasis. (Brown and Goldstein, Science 232:34-47 (1986)). In this application, and in many others, such as those in which an enzyme or hormone is the gene product, it is not necessary to achieve

high levels of expression in order to effect a valuable therapeutic result.

One application of TGT is in the treatment of muscular dystrophy. The genetic basis of the muscular dystrophies is just beginning to be unraveled. The gene related to Duchenne/Becker muscular dystrophy has recently been cloned and encodes a rather large polypeptide, termed dystrophin. Retroviral vectors are unlikely to be useful, because they could not accommodate the rather large size of the cDNA (about 13kb) for dystrophin. Very recently reported work is centered on transplanting myoblasts, but the utility of this approach remains to be determined. Clearly, an attractive approach would be to directly express the dystrophin gene within the muscle of patients with Duchennes. Since most patients die from respiratory failure, the muscles involved with respiration would be a primary target.

Another application is in the treatment of cystic fibrosis. The gene for cystic fibrosis was recently identified (Goodfellow, P. *Nature*, 341(6238):102-3 (Sept. 14, 1989); Rommens, J. et al. *Science*, 245(4922):1059-1065 (September 8, 1989); Beardsley, T. et al., *Scientific American*, 261(5):28-30 (1989)). Significant amelioration of the symptoms should be attainable by the expression of the dysfunctional polypeptide within the appropriate lung cells. The bronchial epithelial cells are postulated to be appropriate target lung cells and they could be accessible to gene transfer following instillation of genes into the lung. Since cystic fibrosis is an autosomal recessive disorder one would need to achieve only about 5% of normal levels of the cystic fibrosis gene product in order to significantly ameliorate the pulmonary symptoms.

Biochemical genetic defects of intermediary metabolism can also be treated by TGT. These diseases include phenylketonuria, galactosemia, maple-syrup urine disease, homocystinuria, propionic acidemia, methylmalonic acidemia, and adenosine deaminase deficiency. The pathogenesis of disease in most of these disorders fits the phenylketonuria (PKU) model of a circulating toxic metabolite. That is, because of an enzyme block, a biochemical, toxic to the body, accumulates in body fluids. These disorders are ideal for gene therapy for a number of reasons. First, only 5% of normal levels of enzyme activity would have to be attained in order to significantly clear enough of the circulating toxic metabolite so that the patient is significantly improved. Second, the transferred gene could most often be expressed in a variety of tissues and still be able to clear the toxic biochemical.

Reversible gene therapy can also be used in treatment strategies requiring intracytoplasmic or intranuclear polypeptide expression. Some polypeptides are known that are capable of regulating transcription by binding to specific promoter regions on nuclear DNA. Other polypeptides bind to RNA, regulating its degradation, transport from the nucleus, or translation efficiency. Polypeptides of this class must be delivered intracellularly for activity. Extracellular delivery of recombinant transcriptional or translational regulatory polypeptides would not be expected to have biological activity, but functional delivery of the DNA or RNA by TGT would be active. Representative polypeptides of this type that would benefit from TGT would include *NEF*, *TAT*, steroid receptor and the retinoid receptor.

Gene therapy can be used in a strategy to increase the resistance of an AIDS patient to HIV infection. Introducing an AIDS resistance gene, such as, for example, the *NEF* gene or the soluble CD4 gene to prevent budding, into an AIDS patient's T cells will render his T cells less capable of producing active AIDS virus, thus sparing the cells of the immune system and improving his ability to mount a T cell dependent immune response. The virus-resistant cells will have a selective advantage over the normal cells, and eventually repopulate the patient's lymphatic system. DNA systemic delivery to macrophages or other target cells can be used. Although this strategy would not be expected to eradicate virus in the macrophage reservoir, it will increase the level of T cells and improve the patient's immune response.

In all of the systemic strategies presented herein, an effective naked DNA or mRNA dosage will generally be in the range of from about 0.05 $\mu\text{g/kg}$ to about 50 mg/kg , usually about 0.005-5 mg/kg . However, as will be appreciated, this dosage will vary in a manner apparent to those of skill in the art according to the activity of the polypeptide coded for by the naked DNA or mRNA and the particular polypeptide used. For delivery of adenosine deaminase to mice or humans, for example, adequate levels of translation are achieved with a naked DNA or mRNA dosage of about 0.5 to 5 mg/kg . See Example 10. From this information, dosages for other polypeptides of known activity can be readily determined.

Diseases which result from deficiencies of critical polypeptides may be appropriately treated by introducing into specialized cells, naked DNA or mRNA coding for these polypeptides. A variety of growth factors such as nerve growth factor and fibroblast growth factor have been shown to affect neuronal cell survival in animal models of Alzheimer's disease. In the aged rat model, NGF infusions have reversed the loss of cholinergic neurons. In the fimbria-fornix lesion rat, NGF infusions or secretion from genetically-modified fibroblasts have also avoided the loss of cholinergic function. Cholinergic activity is diminished in patients with Alzheimer's. The expression within the brain of transduced genes expressing growth factors could reverse the loss of function of specific neuronal groups.

Introduction of naked DNA or mRNA by transfection of the gene for neuronal growth factor into cells lining the cranial cavity can be used in accordance with the present invention in the treatment of Alzheimer's disease. In particular, the present invention may be used to treat this disease by intracranial injection of from about 10 μg to about 100 μg of naked DNA or mRNA into the parenchyma through use of a stereotaxic apparatus. Specifically, the injection is targeted to the cholinergic neurons in the medial septum. The naked DNA or mRNA injection is repeated every 1-3 days for 5' capped, 3' polyadenylated mRNA, and every week to 21 days for circular mRNA, and every 30 to 60 days for DNA. Epi-

somal DNA, for example, could be active for a number of months, and reinjection would only be necessary upon notable regression by the patient.

In addition, the enzymes responsible for neurotransmitter synthesis could be expressed from transduced genes. For example, the gene for choline acetyl transferase could be expressed within the brain cells (neurons or glial) of specific areas to increase acetylcholine levels and improve brain function.

The critical enzymes involved in the synthesis of other neurotransmitters such as dopamine, norepinephrine, and GABA have been cloned and are available. The critical enzymes could be locally increased by gene transfer into a localized area of the brain. The increased productions of these and other neurotransmitters would have broad relevance to manipulation of localized neurotransmitter function and thus to a broad range of brain disease in which disturbed neurotransmitter function plays a crucial role. Specifically, these diseases could include schizophrenia and manic-depressive illnesses and Parkinson's Disease. It is well established that patients with Parkinson's suffer from progressively disabled motor control due to the lack of dopamine synthesis within the basal ganglia. The rate limiting step for dopamine synthesis is the conversion of tyrosine to L-DOPA by the enzyme, tyrosine hydroxylase. L-DOPA is then converted to dopamine by the ubiquitous enzyme, DOPA decarboxylase. That is why the well-established therapy with L-DOPA is effective (at least for the first few years of treatment). Gene therapy could accomplish the similar pharmacologic objective by expressing the genes for tyrosine hydroxylase and possible DOPA decarboxylase as well. Tyrosine is readily available within the CNS.

The genetic form of alpha-1-antitrypsin deficiency can result in both liver and lung disease. The liver disease, which is less common, is caused by the accumulation of an abnormal polypeptide and would be less amenable to gene therapy. The pulmonary complications, however, would be amenable to the increased expression of alpha-1-antitrypsin within the lung. This should prevent the disabling and eventually lethal emphysema from developing.

Alpha-1-antitrypsin deficiency also occurs in tobacco smokers since tobacco smoke decreases alpha-1-antitrypsin activity and thus serine protease activity that leads to emphysema. In addition, some recent data links tobacco smoke's anti-trypsin effect to aneurysms of the aorta. Aneurysms would also be preventable by raising blood levels of anti-1-antitrypsin since this would decrease protease activity that leads to aneurysms.

Patients with degenerative disease of the lung could also benefit from the expression of enzymes capable of removing other toxic metabolites which tend to accumulate in diseased lung tissue. Superoxide dismutase and catalase could be delivered by TGT to ameliorate these problems.

TGT can be used in treatment strategies requiring the delivery of cell surface receptors. It could be argued that there is no need to decipher methodology for functional *in vivo* delivery of genes. There is, after all, an established technology for the synthesis and large scale production of polypeptides, and polypeptides are the end product of gene expression. This logic applies for many polypeptide molecules which act extracellularly or interact with cell surface receptors, such as tissue plasminogen activator (TPA), growth hormone, insulin, interferon, granulocyte-macrophage colony stimulating factor (GM-CSF), erythropoietin (EPO), etc. However, the drug delivery problems associated with properly delivering a recombinant cell surface receptor to be inserted in the plasma membrane of its target cell in the proper orientation for a functional receptor have hitherto appeared intractable.

When naked DNA or RNA coding for a cell surface receptor is delivered intracellularly as described herein, the resulting polypeptide can be efficiently and functionally expressed on the target cell surface. If the problem of functional delivery of recombinant cell surface receptors remains intractable, then the only way of approaching this therapeutic modality will be through gene delivery. Similar logic for nuclear or cytoplasmic regulation of gene expression applies to nuclear regulatory factor bound to DNA to regulate (up or down) RNA transcription and to cytoplasmic regulatory factors which bind to RNA to increase or decrease translational efficiency and degradation. TGT could in this way provide therapeutic strategies for the treatment of cystic fibrosis, muscular dystrophy and hypercholesterolemia.

Elevated levels of cholesterol in the blood may be reduced in accordance with the present invention by supplying naked mRNA coding for the LDL surface receptor to hepatocytes. A slight elevation in the production of this receptor in the liver of patients with elevated LDL will have significant therapeutic benefits. Therapies based on systemic administration of recombinant polypeptides are not able to compete with the present invention, because simply administering the recombinant polypeptide could not get the receptor into the plasma membrane of the target cells. The receptor must be properly inserted into the membrane in order to exert its biological effect. It is not usually necessary to regulate the level of receptor expression; the more expression the better. This simplifies the molecular biology involved in preparation of the naked mRNA for use in the present invention. The level of LDL receptor in the liver will increase gradually as the number of injections increases. Higher liver LDL receptor levels will lead to therapeutic lowering of LDL and cholesterol. An effective naked mRNA dose will generally be from about 0.1 to about 5 mg/kg.

Other examples of beneficial applications of TGT include the introduction of the thymidine kinase gene into macrophages of patients infected with the HIV virus. Introduction of the thymidine kinase gene into the macrophage reservoir will render those cells more capable of phosphorylating AZT. This tends to overcome their resistance to AZT therapy, making AZT capable of eradicating the HIV reservoir in macrophages. This will render the AZT resistant cells subject to treatment with AZT. The thymidine kinase therapy can also be focused by putting the thymidine kinase gene under

the control of the HTLV III promoter. According to this strategy, the thymidine kinase would only be synthesized on infection of the cell by HIV virus, and the production of the *lat* polypeptide which activates the promoter. An analogous therapy would supply cells with the gene for diphtheria toxin under the control of the same HTLV III promoter, with the lethal result occurring in cells only after HIV infection.

5 These AIDS patients could also be treated by supplying the interferon gene to the macrophages according to the TGT method. Increased levels of localized interferon production in macrophages could render them more resistant to the consequences of HIV infection. While local levels of interferon would be high, the overall systemic levels would remain low, thereby avoiding the systemic toxic effects like those observed after recombinant interferon administration.

Various cancers may be treated using TGT by supplying a diphtheria toxin gene on a DNA template with a tissue
10 specific enhancer to focus expression of the gene in the cancer cells. Intracellular expression of diphtheria toxin kills cells. These promoters could be tissue-specific such as using a pancreas-specific promoter for the pancreatic cancer. A functional diphtheria toxin gene delivered to pancreatic cells could eradicate the entire pancreas. This strategy could be used as a treatment for pancreatic cancer. The patients would have no insurmountable difficulty surviving without a pancreas. The tissue specific enhancer would ensure that expression of diphtheria toxin would only occur in pancreatic
15 cells. The infusion would occur on some dosing schedule for as long as necessary to eradicate the pancreatic tissue. Other lethal genes besides diphtheria toxin could be used with similar effect, such as genes for ricin or cobra venom factor or enterotoxin.

Also, one could treat cancer by using a cell-cycle specific promoter that would only kill cells that are rapidly cycling (dividing) such as cancer cells. Cell-cycle specific killing could also be accomplished by designing mRNA encoding
20 killer polypeptides that are stable only in cycling cells (i.e. histone mRNA that is only stable during S phase). Also, one could use developmental-specific promoters such as the use of alpha-fetoprotein that is only expressed in fetal liver cells and in hepatoblastoma cells that have dedifferentiated into a more fetal state.

One could also treat specialized cancers by the transfer of genes such as the retinoblastoma gene (and others of that family) that suppress the cancer properties of certain cancers.

25 The TGT strategy can be used to provide a controlled, sustained delivery of polypeptides. Conventional drugs, as well as recombinant polypeptide drugs, can benefit from controlled release devices. The purpose of the controlled release device is to deliver drugs over a longer time period, so that the number of doses required is reduced. This results in improvements in patient convenience and compliance. There are a wide variety of emerging technologies that are intended to achieve controlled release.

30 TGT can be used to obtain controlled delivery of therapeutic polypeptides. Regulated expression can be obtained by using suitable promoters, including cell-specific promoters. Suitable polypeptides may be delivered, for example, growth hormone, insulin, interleukins, interferons, GM-CSF, EPO, and the like. Depending on the specific application, the naked DNA or an RNA construct selected can be designed to result in a gene product that is secreted from the injected cells and into the systemic circulation.

35 TGT can also comprise the controlled delivery of therapeutic polypeptides which is achieved by including with the naked polynucleotide to be expressed in the cell, an additional naked polynucleotide which codes for a regulatory polypeptide which controls processes of transcription and translation. These naked polynucleotides comprise those which operate either to up regulate or down regulate polypeptide expression, and exert their effects either within the nucleus or by controlling polypeptide translation events in the cytoplasm.

40 The T7 polymerase gene can be used in conjunction with a gene of interest to obtain longer duration of effect of TGT. Episomal DNA such as that obtained from the origin of replication region for the Epstein Barr virus can be used, as well as that from other origins of replication which are functionally active in mammalian cells, and preferably those that are active in human cells. This is a way to obtain expression from cells after many cell divisions, without risking unfavorable integration events that are common to retrovirus vectors. Controlled release of calcitonin could be obtained
45 if a calcitonin gene under the control of its own promoter could be functionally introduced into some site, such as liver or skin. Cancer patients with hypercalcemia would be a group to whom this therapy could be applied.

Other gene therapies using TGT can include the use of a naked polynucleotide that has a therapeutic effect without being translated into a polypeptide. For example, TGT can be used in the delivery of naked polynucleotides encoding anti-sense polynucleotides for turning off the expression of specific genes. Conventional anti-sense methodology suffers from poor efficacy, in part, because the oligonucleotide sequences delivered are too short. With TGT, however, full
50 length polynucleotides encoding anti-sense sequences can be delivered as easily as short oligomers. Anti-sense polynucleotides encoded by naked polynucleotides encode an RNA that hybridizes to an endogenous sequence, interfering with translation. Other uses of TGT in this vein include delivering a naked polynucleotide that encodes a tRNA or rRNA to replace a defective or deficient endogenous tRNA or rRNA, the presence of which causes the pathological condition.

55 Cell-specific promoters can also be used to permit expression of the gene only in the target cell. For example, certain genes are highly promoted in adults only in particular types of tumors. Similarly, tissue-specific promoters for specialized tissue, e.g., lens tissue of the eye, have also been identified and used in heterologous expression systems.

Beyond the therapies described, the medicaments of the invention can be used to deliver naked polynucleotides to

animal stock to increase production of milk in dairy cattle or muscle mass in animals that are raised for meat.

Naked DNA and mRNA Vaccines

According to the uses of the invention, both expressible naked DNA and mRNA can be delivered to cells to form therein a polypeptide translation product. If the nucleic acids contain the proper control sequences, they will direct the synthesis of relatively large amounts of the encoded polypeptide. When the naked DNA and mRNA delivered to the cells codes for an immunizing polypeptide, the uses can be applied to achieve improved and more effective immunity against infectious agents, including intracellular viruses, and also against tumor cells.

Since the immune systems of all vertebrates operate similarly, the applications described can be implemented in all vertebrate systems, comprising mammalian and avian species, as well as fish.

The medicaments of the invention may be applied by direct injection of the naked polynucleotide into cells of the animal *in vivo*. The naked polynucleotides may be delivered to various cells of the animal body, including muscle, skin, brain, lung, liver, spleen, or to the cells of the blood. Delivery of the naked polynucleotides directly *in vivo* is preferably to the cells of muscle or skin. The naked polynucleotides may be injected into muscle or skin using an injection syringe. They may also be delivered into muscle or skin using a vaccine gun.

Vaccination with nucleic acids containing a gene for an antigen may also provide a way to specifically target the cellular immune response. Cells expressing polypeptides which are secreted will enter the normal antigen processing pathways and produce both a humoral and cytotoxic response. The response to polypeptides which are not secreted is more selective. Non-secreted polypeptides synthesized in cells expressing only class I MHC molecules are expected to produce only a cytotoxic vaccination. Expression of the same antigen in cells bearing both class I and class II molecules may produce a more vigorous response by stimulating both cytotoxic and helper T cells. Enhancement of the immune response may also be possible by injecting the gene for the antigen along with a polypeptide fragment of the antigen. The antigen is presented via class I MHC molecules to the cellular immune system while the polypeptide is presented via class II MHC molecules to stimulate helper T cells. In any case, this use provides a way to stimulate and modulate the immune response in a way which has not previously been possible.

A major disadvantage of subunit vaccines is that glycoprotein antigens are seldom modified correctly in the recombinant expression systems used to make the antigens. Introducing the gene for a glycoprotein antigen will insure that the polypeptide product is synthesized, modified and processed in the same species and cells that the pathogen polypeptide would be. Thus, the expression of a gene for a human viral glycoprotein will contain the correct complement of sugar residues. This is important because it has been demonstrated that a substantial component of the neutralizing antibodies in some viral systems are directed at carbohydrate epitopes.

Any appropriate antigen which is a candidate for an immune response, whether humoral or cellular, can be used in its nucleic acid form. The source of the cells could be fibroblasts which provide a convenient source of cells expressing only class I MHC molecules. Alternatively, peripheral blood cells can provide a source of cells containing both class I and class II MHC proteins. Bone marrow cells can provide a source of less differentiated lymphoid cells. In all cases the cell will be transfected either with naked DNA containing a gene for the antigen or by the appropriate capped and polyadenylated naked mRNA transcribed from that gene or a circular naked RNA, chemically modified naked RNA, or a naked RNA which does not require 5' capping. The choice of the transfecting naked polynucleotide may depend on the duration of expression desired. For vaccination purposes, a reversible expression of the immunogenic polypeptide, as occurs on naked mRNA transfection, is preferred.

There are several applications to the approach of targeting cellular immunity. The first is vaccination against viruses in which antibodies are known to be required or to enhance viral infection. There are two strategies that can be applied here. One can specifically target the cellular pathway during immunization thus eliminating the enhancing antibodies. Alternatively one can vaccinate with the gene for a truncated antigen which eliminates the humoral epitopes which enhance infectivity.

The use of naked DNA or mRNA vaccine therapy could similarly provide a means to provoke an effective cytotoxic T-cell response to weakly antigenic tumors. We propose, for example, that if a tumor-specific antigen were expressed by naked mRNA inside a cell in an already processed form, and incorporated directly into the Class I molecules on the cell surface, a cytotoxic T cell response would be elicited.

A second application is that this approach provides a method to treat latent viral infections. Several viruses (for example, Hepatitis B, HIV and members of the Herpes virus group) can establish latent infections in which the virus is maintained intracellularly in an inactive or partially active form. There are few ways of treating such infections. However, by inducing a cytolytic immunity against a latent viral polypeptide, the latently infected cells will be targeted and eliminated.

A related application of this approach is to the treatment of chronic pathogen infections. There are numerous examples of pathogens which replicate slowly and spread directly from cell to cell. These infections are chronic, in some cases lasting years or decades. Examples of these are the slow viruses (e.g. Visna), the Scrapie agent and HIV. One

can eliminate the infected cells by inducing a cellular response to polypeptides of the pathogen.

Finally, this approach may also be applicable to the treatment of malignant disease. Vaccination to mount a cellular immune response to a polypeptide specific to the malignant state, be it an activated oncogene, a fetal antigen or an activation marker, will result in the elimination of these cells.

5 The use of naked DNA/mRNA vaccines could in this way greatly enhance the immunogenicity of certain viral polypeptides, and cancer-specific antigens, that normally elicit a poor immune response. The naked mRNA vaccine technique should be applicable to the induction of cytotoxic T cell immunity against poorly immunogenic viral polypeptides from the Herpes viruses, non-A, non-B hepatitis, and HIV, and it would avoid the hazards and difficulties associated with *in vitro* propagation of these viruses. For cell surface antigens, such as viral coat polypeptides (e.g., HIV gp120), the antigen would be expressed on the surface of the target cell in the context of the major histocompatibility complex (MHC), which would be expected to result in a more appropriate, vigorous and realistic immune response. It is this factor that results in the more efficacious immune responses frequently observed with attenuated virus vaccines. Delivery of a single antigen gene by TGT would be much safer than attenuated viruses, which can result in a low frequency of disease due to inadequate attenuation.

15 There is an additional advantage of TGT which can be exploited during the vaccine development phase. One of the difficulties with vaccine development is the requirement to screen different structural variants of the antigen, for the optimal immune response. If the variant is derived from a recombinant source, the polypeptide usually must be expressed and purified before it can be tested for antigenicity. This is a laborious and time consuming process. With *in vitro* mutagenesis, it is possible to obtain and sequence numerous clones of a given antigen. If these antigens can be screened for antigenicity at the DNA or RNA level by TGT, the vaccine development program could be made to proceed much faster.

20 Finally, in the case of the naked DNA/mRNA vaccines, the polypeptide antigen is never exposed directly to serum antibody, but is always produced by the transfected cells themselves following translation of the mRNA. Hence, anaphylaxis should not be a problem. Thus, the present invention permits the patient to be immunized repeatedly without the fear of allergic reactions. The use of the naked DNA/mRNA vaccines of the present invention makes such immunization possible.

One can easily conceive of ways in which this technology can be modified to enhance still further the immunogenicity of antigens. T cell immunization can be augmented by increasing the density of Class I and Class II histocompatibility antigens on the macrophage or other cell surface and/or by inducing the transfected cell to release cytokines that promote lymphocyte proliferation. To this end, one may incorporate in the same injectable preparation that contains mRNA for the antigen, other mRNA species that encode interferons or interleukin-1. These cytokines are known to enhance macrophage activation. Their systemic use has been hampered because of side effects. However, when encoded in mRNA, along with mRNA for antigen, they should be expressed only by those cells that co-express antigen. In this situation, the induction of T cell immunity can be enhanced greatly.

35 Therapeutic Formulations

Naked polynucleotide salts: Preparation of pharmaceutically acceptable salts of the naked polynucleotides described herein is included within the scope of the invention. Such salts may be prepared from pharmaceutically acceptable non-toxic bases including organic bases and inorganic bases. Salts derived from inorganic bases include sodium, potassium, lithium, ammonium, calcium, magnesium, and the like. Salts derived from pharmaceutically acceptable organic non-toxic bases include salts of primary, secondary, and tertiary amines, basic amino acids, and the like. For a helpful discussion of pharmaceutical salts, see S. M. Berge et al., *Journal of Pharmaceutical Sciences* 66:1-19 (1977).

45 Naked polynucleotides for injection, a preferred route of delivery, may be prepared in unit dosage form in ampules, or in multidose containers. The naked polynucleotides may be present in such forms as suspensions, solutions, or emulsions in oily or preferably aqueous vehicles. Alternatively, the naked polynucleotide salt may be in lyophilized form for reconstitution, at the time of delivery, with a suitable vehicle, such as sterile pyrogen-free water. Both liquid as well as lyophilized forms that are to be reconstituted will comprise agents, preferably buffers, in amounts necessary to suitably adjust the pH of the injected solution. For any parenteral use, particularly if the formulation is to be administered intravenously, the total concentration of solutes should be controlled to make the preparation isotonic, hypotonic, or weakly hypertonic. Nonionic materials, such as sugars, are preferred for adjusting tonicity, and sucrose is particularly preferred. Any of these forms may further comprise suitable formulatory agents, such as starch or sugar, glycerol or saline. The compositions per unit dosage, whether liquid or solid, may contain from 0.1% to 99% of naked polynucleotide material.

55 The unit dosage ampules or multidose containers, in which the naked polynucleotides are packaged prior to use, may comprise an hermetically sealed container enclosing an amount of naked polynucleotide or solution containing a naked polynucleotide suitable for a pharmaceutically effective dose thereof, or multiples of an effective dose. The naked polynucleotide is packaged as a sterile formulation, and the hermetically sealed container is designed to preserve sterility.

rility of the formulation until use.

The container in which the naked polynucleotide is packaged is labeled, and the label bears a notice in the form prescribed by a governmental agency, for example the Food and Drug Administration, which notice is reflective of approval by the agency under Federal law, of the manufacture, use, or sale of the polynucleotide material therein for human administration.

Federal law requires that the use of pharmaceutical agents in the therapy of humans be approved by an agency of the Federal government. Responsibility for enforcement is the responsibility of the Food and Drug Administration, which issues appropriate regulations for securing such approval, detailed in 21 U.S.C. 301-392. Regulation for biologic material, comprising products made from the tissues of animals is provided under 42 U.S.C 262. Similar approval is required by most foreign countries. Regulations vary from country to country, but the individual procedures are well known to those in the art.

Dosage and Route of Administration

The dosage to be administered depends to a large extent on the condition and size of the subject being treated as well as the frequency of treatment and the route of administration. Regimens for continuing therapy, including dose and frequency may be guided by the initial response and clinical judgment. The parenteral route of injection into the interstitial space of tissues is preferred, although other parenteral routes, such as inhalation of an aerosol formulation, may be required in specific administration, as for example to the mucous membranes of the nose, throat, bronchial tissues or lungs.

In preferred protocols, a formulation comprising the naked polynucleotide in an aqueous carrier is injected into tissue in amounts of from 10 µl per site to about 1 ml per site. The concentration of naked polynucleotide in the formulation is from about 0.1 µg/ml to about 20 mg/ml.

Regulation of TGT

Just as naked DNA based gene transfer protocols require appropriate signals for transcribing (promoters, enhancers) and processing (splicing signals, polyadenylation signals) the mRNA transcript, naked mRNA based TGT requires the appropriate structural and sequence elements for efficient and correct translation, together with those elements which will enhance the stability of the transfected naked mRNA.

In general, translational efficiency has been found to be regulated by specific sequence elements in the 5' non-coding or untranslated region (5'UTR) of the RNA. Positive sequence motifs include the translational initiation consensus sequence (GCC)^ACCATGG (Kozak, *Nucleic Acids Res.*15:8125 (1987)) and the 5^G 7 methyl GpppG cap structure (Drummond et al., *Nucleic Acids Res.* 13:7375 (1985)). Negative elements include stable intramolecular 5' UTR stem-loop structures (Muesing et al., *Cell* 48:691(1987)) and AUG sequences or short open reading frames preceded by an appropriate AUG in the 5' UTR (Kozak, *Supra*, Rao et al., *Mol. and Cell. Biol.* 8:284(1988)). In addition, certain sequence motifs such as the beta globin 5' UTR may act to enhance translation (when placed adjacent to a heterologous 5' UTR) by an unknown mechanism. There are also examples of specific 5' UTR sequences which regulate eukaryotic translational efficiency in response to environmental signals. These include the human ferritin 5' UTR (Hentze et al., *Proc. Natl. Acad. Sci. USA* 84:6730 (1987)) and the drosophila *hsp*⁷⁰ 5' UTR (Klemenz et al., *EMBO Journal* 4:2053 (1985)). Finally, there are viral 5' UTR sequences which are able to bypass normal cap dependant translation and translational controls and mediate an efficient translation of viral or chimeric mRNAs (Dolph et al., *J. of Virol.* 62:2059 (1988), Pelletier and Sonenberg, *Nature* 334, 320 (1988)). Naked mRNA based TGT protocols must therefore include appropriate 5' UTR translational elements flanking the coding sequence for the polypeptide of interest.

In addition to translational concerns, mRNA stability must be considered during the development of naked mRNA based TGT protocols. As a general statement, capping and 3' polyadenylation are the major positive determinants of eukaryotic mRNA stability (Drummond, *supra*; Ross, *Mol. Biol. Med.* 5:1(1988)) and function to protect the 5' and 3' ends of the mRNA from degradation. However, regulatory elements which affect the stability of eukaryotic mRNAs have also been defined, and therefore must be considered in the development of naked mRNA TGT protocols. The most notable and clearly defined of these are the uridine rich 3' untranslated region (3' UTR) destabilizer sequences found in many short half-life mRNAs (Shaw and Kamen *Cell* 46:659 (1986)), although there is evidence that these are not the only sequence motifs which result in mRNA destabilization (Kabnick and Housman, *Mol. and Cell. Biol.* 8:3244 (1988)). In addition, specific regulatory sequences which modulate cellular mRNA half life in response to environmental stimuli have also been demonstrated. These include the estrogen mediated modulation of Vitellogenin mRNA stability (Brock and Shapiro, *Cell* 34:207 (1983)), the iron dependant regulation of transferrin receptor mRNA stability (Mullner and Kuhn, *Cell* 53:815 (1988)) which is due to a specific 3' UTR motif, the prolactin mediated control of Casein mRNA stability (Guyette et al., *Cell* 17:1013 (1989)), the regulation of Fibronectin mRNA stability in response to a number of stimuli (Dean et al., *J. Cell. Biol.* 106:2159 (1988)), and the control of Histone mRNA stability (Graves et al., *Cell*

48:615 (1987)). Finally, just as viral RNA sequences have evolved which bypass normal eukaryotic mRNA translational controls, likewise some viral RNA sequences seem to be able to confer stability in the absence of 3' polyadenylation (McGrae and Woodland, *Eur. J. of Biochem.* 116: 467 (1981)). Some 5', such as EMC, according to Example 21, are known to function without a cap. This cacophony of stability modulating elements must also be carefully considered in developing naked mRNA based TGT protocols, and can be used to modulate the effect of a naked mRNA treatment.

The present invention and comparative examples are described below in detail using the 25 examples given below; however, the uses described are broadly applicable as described herein and are not intended to be limited by the Examples. As previously mentioned, examples relating to liposomes and liposome transfection are only by way of comparison and are not encompassed by the present invention. Furthermore, any transfection carried out *in vitro* for subsequent transplantation is also by way of comparison and is not taken to be encompassed by the present invention.

EXAMPLE 1: PREPARATION OF LIPOSOME-FORMING DOTAP

The cationic liposome-forming material 1,2-bis(oleoyloxy)-3-(trimethylammonio)propane (DOTAP) is prepared as reported by L. Stamatas, et al. (*supra*) or H. Eibl, et al. (*supra*).

Briefly, Stamatas, et al. report that 1 mmol of 3-bromo-1,2-propanediol (Aldrich) was acylated for 48 hours at 20°C with 3 mmol of oleyl chloride (freshly prepared from oleic acid and oxaloyl chloride) in dry, alcohol-free diethyl ether (20 ml) containing 5 mmol of dry pyridine. The precipitate of pyridinium hydrochloride was filtered off, and the filtrate was concentrated under nitrogen and redissolved in 10 ml of hexane. The hexane solution was washed 3 times with an equal volume of 1:1 methanol/0.1 N aqueous HCOONa, pH 3.0, 3 times with 1:1 methanol/0.1 N aqueous NaOH, and 1 time with 1% aqueous NaCl. The crude 3-bromo-1,2-bis-(oleoyloxy)propane was then stirred for 72 hours in a sealed tube with a solution of 15% trimethylamine in dry dimethyl sulfoxide (30 ml) at 25°C. The products of this reaction were dissolved in chloroform (200 ml), which was repeatedly washed with 1:1 methanol/100 mM aqueous HCOONa, pH 3.0, and then evaporated *in vacuo* to yield a light yellow oil. This material was purified on a column of silicic acid (Bio-Sil A, Bio-Rad Laboratories), eluting with a 0-15% gradient of methanol in chloroform to give the desired product in pure form at 9-10% methanol. The purified product was a colorless, viscous oil that migrates with an R_f of 0.4 on thin layer chromatography plates (silica gel G) that were developed with 50:15:5:5:2 CHCl₃/acetone/CH₃OH/CH₃COOH/H₂O.

EXAMPLE 2: PREPARATION OF PLASMIDS FOR MAKING DNA TEMPLATES FOR ANY GENE OF INTEREST

Suitable template DNA for production of mRNA coding for a desired polypeptide may be prepared in accordance with standard recombinant DNA methodology. As has been previously reported (P. Kreig, et al., *Nucleic Acids Res.* 12:7057-7070 (1984)), a 5' cap facilitates translation of the mRNA. Moreover, the 3' flanking regions and the poly A tail are believed to increase the half life of the mRNA *in vivo*.

The readily-available SP6 cloning vector pSP64T provides 5' and 3' flanking regions from β -globin, an efficiently translated mRNA. The construction of this plasmid is detailed by Kreig, et al. (*supra*). Any cDNA containing an initiation codon can be introduced into this plasmid, and mRNA can be prepared from the resulting template DNA. This particular plasmid can be cut with BglII to insert any desired cDNA coding for a polypeptide of interest.

Although good results can be obtained with pSP64T when linearized and then transcribed *in vivo* with SP6 RNA polymerase, we prefer to use the xenopus β -globin flanking sequences of pSP64T with phage T7 RNA polymerase. These flanking sequences are purified from pSP64T as the small (approx. 150 bp) HindIII to EcoRI fragment. These sequences are then inserted into a purified linear HindIII/EcoRI fragment (approx. 2.9k bp) from pIBI 31 (commercially available from International Biotechnologies, Inc., Newhaven, Connecticut 06535) with T4 DNA ligase. Resulting plasmids, designated pXBG, are screened for orientation and transformed into *E. coli*. These plasmids are adapted to receive any gene of interest at a unique BglII restriction site, which is situated between the two xenopus β -globin sequences.

EXAMPLE 3: PREPARATION OF PLASMID CODING FOR CHLORAMPHENICOL ACETYLTRANSFERASE

A convenient marker gene for demonstrating *in vivo* expression of exogenous polynucleotides is chloramphenicol acetyltransferase, CAT. A plasmid pSP-CAT containing the CAT gene flanked by the xenopus β -globin 5' and 3' sequences was produced by adding the CAT gene into the BglII site of pSP64T. We used CAT gene in the form of the small BamHI/HindIII fragment from pSV2-CAT (available from the American Type Culture Collection, Rockville, Maryland, Accession No. 37155). However, the CAT gene is commonly used in molecular biology and is available from numerous sources. Both the CAT BamHI/HindIII fragment and the BglII-cleaved pSP64T were incubated with the Klenow fragment to generate blunt ends, and were then ligated with T4 DNA ligase to form pSP-CAT.

The small PstI/HindIII fragment was then generated and purified, which comprises the CAT gene between the 5'

and 3' β -globin flanking sequences of pSP64T. pIB131 (International Biotechnologies, Inc.) was cleaved with PstI and HindIII, and the long linear sequence was purified. This fragment was then combined with the CAT-gene containing sequence and the fragments were ligated with T4 DNA ligase to form a plasmid designated pT7CAT An. Clones are selected on the basis of β -galactosidase activity with Xgal and ampicillin resistance.

EXAMPLE 4: PREPARATION OF PURIFIED DNA TEMPLATE

The plasmid DNA from Example 3 is grown up and prepared as per Maniatis (supra), except without RNase, using 2 CsCl spins to remove bacterial RNA. Specifically, *E. coli* containing pT7CAT An from Example 3 was grown up in ampicillin-containing LB medium. The cells were then pelleted by spinning at 5000 rpm for 10 min. in a Sorvall RC-5 centrifuge (E.I. DuPont, Burbank, California 91510), resuspended in cold TE, pH 8.0, centrifuged again for 10 min. at 5000 rpm., resuspended in a solution of 50 mM glucose, 25 mM Tris-Cl pH 8.0, 10 mM EDTA, and 40 mg/ml lysozyme. After incubation for 5 to 10 minutes with occasional inversion, 0.2 N NaOH containing 1% SDS was added, followed after 10 minutes at 0° C with 3 M potassium acetate and 2 M acetic acid. After 10 more minutes, the material was again centrifuged at 6000 rpm, and the supernatant was removed with a pipet. The pellet was then mixed into 0.6 vol. isopropanol (-20° C), mixed, and stored at -20° C for 15 minutes. The material was then centrifuged again at 10,000 rpm for 20 min., this time in an HB4 swinging bucket rotor apparatus (DuPont, supra) after which the supernatant was removed and the pellet was washed in 70% EtOH and dried at room temperature. Next, the pellet was resuspended in 3.5 ml TE, followed by addition of 3.4 g CsCl and 350 μ l of 5 mg/ml EtBr. The resulting material was placed in a quick seal tube, filled to the top with mineral oil. The tube was spun for 3.5 hours at 80,000 rpm in a VTi80 centrifuge (Beckman Instruments, Pasadena, California, 91051). The band was removed, and the material was centrifuged again, making up the volume with 0.95 g CsCl/ml and 0.1 ml or 5 mg/ml EtBr/ml in TE. The EtBr was then extracted with an equal volume of TE saturated N-Butanol after adding 3 volumes of TE to the band, discarding the upper phase until the upper phase is clear. Next, 2.5 vol. EtOH was added, and the material was precipitated at -20 C for 2 hours. The resultant DNA precipitate is used as a DNA template for preparation of mRNA *in vitro*.

EXAMPLE 5: PREPARATION OF mRNA FOR TRANSFECTION

The DNA from Example 4 was linearized downstream of the poly A tail with a 5-fold excess of PstI. The linearized DNA was then purified with two phenol/chloroform extractions, followed by two chloroform extractions. DNA was then precipitated with NaOAc (0.3 M) and 2 volumes of EtOH. The pellet was resuspended at about 1 mg/ml in DEP-treated deionized water.

Next, a transcription buffer was prepared, comprising 400 mM Tris HCl (pH 8.0), 80 mM MgCl₂, 50 mM DTT, and 40 mM spermidine. Then, the following materials were added in order to one volume of DEP-treated water at room temperature: 1 volume T7 transcription buffer, prepared above; rATP, rCTP, and rUTP to 1 mM concentration; rGTP to 0.5 mM concentration; 7meG(5')ppp(5')G cap analog (New England Biolabs, Beverly, Massachusetts, 01951) to 0.5 mM concentration; the linearized DNA template prepared above to 0.5 mg/ml concentration; RNasin (Promega, Madison, Wisconsin) to 2000 U/ml concentration; and T7 RNA polymerase (N.E. Biolabs) to 4000 U/ml concentration.

This mixture was incubated for 1 hour at 37 C. The successful transcription reaction was indicated by increasing cloudiness of the reaction mixture.

Following generation of the mRNA, 2 U RQ1 DNase (Promega) per microgram of DNA template used was added and was permitted to digest the template for 15 minutes. Then, the RNA was extracted twice with chloroform/phenol and twice with chloroform. The supernatant was precipitated with 0.3 M NaOAc in 2 volumes of EtOH, and the pellet was resuspended in 100 μ l DEP-treated deionized water per 500 μ l transcription product. This solution was passed over an RNase-free Sephadex G50 column (Boehringer Mannheim #100 411). The resultant mRNA was sufficiently pure to be used in transfection of vertebrates *in vivo*.

EXAMPLE 6: PREPARATION OF LIPOSOMES

A solution of 10 mg dioleoyl phosphatidylethanolamine (PE) and 10 mg DOTAP (from Example 1) in 1 ml chloroform is evaporated to dryness under a stream of nitrogen, and residual solvent is removed under vacuum overnight. Liposomes are prepared by resuspending the lipids in deionized water (2 ml) and sonicating to clarity in a closed vial. These preparations are stable for at least 6 months.

Polynucleotide complexes were prepared by mixing 0.5 ml polynucleotide solution (e.g., from Example 5) at 0.4 mg/ml by slow addition through a syringe with constant gentle vortexing to a 0.5 ml solution of sonicated DOTMA/PE or DOTAP/PE liposomes at 20 mg/ml, at room temperature. This procedure results in positively charged complexes which will spontaneously deliver the polynucleotide into cells *in vivo*. Different ratios of positively charged liposome to polynucleotide can be used to suit the particular need in any particular situation. Alternatively, as reported by Felgner, et al.

(supra), it may be advantageous to dilute the polynucleotide (DNA or RNA) with Hepes buffered saline (150 mM NaCl; 20 mM Hepes, pH 7.4) prior to combining the materials to spontaneously form liposome/polynucleotide complexes. In many instances, however, the use of solutions having low ionic strength (such as sucrose) instead of saline solution is believed to be preferable; in particular, it is believed that such solutions facilitate delivery of polynucleotide to the cell by minimizing precipitation of polynucleotide/lipid complex.

EXAMPLE 7: *IN VIVO* EXPRESSION OF LIPOSOMALLY AND NON-LIPOSOMALLY INTRODUCED mRNA IN THE RAT

The ability of mRNA coding for chloramphenicol acetyl transferase (CAT) to transfect cells *in vivo* and the subsequent expression of the CAT protein was demonstrated by directly injecting 0.200 μ l of each of the formulations below, prepared as indicated, into the abdominal muscle of rats, forming a bleb. Six replicates of each formulation were tested. After 12 to 14 h, the segment of the abdominal muscle into which the injection was made, weighing approximately 0.1 to 0.2 grams, was excised, minced, and placed in a 1.5 ml disposable mortar (Kontes, Morton Grove, Illinois) together with 200 ml of the aqueous formulation having the following components: 20 mM Tris, pH 7.6; 2 mM $MgCl_2$; and 0.1% Triton X-100 surfactant. The contents of the mortar were then ground for 1 minute with a disposable pestle. The mortar was then covered (with Parafilm) and placed in a 1 liter Parr cell disrupter bomb (Parr Instrument Company, Moline, Illinois) and pressurized to 6 atmospheres with nitrogen at 4°C. After 30 minutes, the pressure was quickly released to disrupt the tissue and produce a crude lysate. The lysate was then centrifuged in a microcentrifuge at 13,000 rpm, 4°C, for 10 minutes. The supernatant was then decanted and stored at -20°C until analyzed.

The lysates were then assayed for the presence of the CAT protein by thin-layer chromatography. First, 75 μ l of each sample (the supernatant prepared above) was incubated for two hours at 37°C with 5 μ l C^{14} chloramphenicol (Amersham); 20 μ l 4 mM Acetyl CoA; and 50 μ l 1 M Tris, pH 7.8. Thereafter, 20 μ l of 4 mM Acetyl CoA was added, and the mixture was again incubated for 2 hours at 37°C. The resulting solution was extracted with 1 ml EtOAc, and the organic phase was removed and lyophilized in a vacuum centrifuge (SpeedVac, Savant Co.). The pellet was resuspended in 20 μ l EtOAc, and was spotted onto a silica gel thin layer chromatography plate. The plate was developed for 45 minutes in 95% chloroform/5% methanol, was dried, and was sprayed with a radioluminescent indicator (Enhance Spray for Surface Radiography, New England Nuclear Corp.). The plate was then sandwiched with Kodak XAR5 film with overnight exposure at -70°C, and the film was developed per manufacturer's instructions. The following results were obtained:

| FORMULATION | mRNA Expression (No. positive/total) |
|-----------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| 1. 1 ml Optimem; 37.5 μ g DOTMA | 0/6 |
| 2. 1 ml Optimem; 15 μ g CAT RNA | 3/6 |
| 3. Formulation 1 plus 15 μ g CAT RNA | 4/6 |
| 4. 10% Sucrose; 37.5 μ g DOTMA; 15 μ g CAT RNA | 3/6 |
| 5. 10% Sucrose; 187 μ g DOTMA; 75 μ g CAT RNA | 0/6 |
| Optimem: Serum-free media (Gibco Laboratories, Life Technologies, Inc, Grand Island, N.Y. 14072) | |
| DOTMA: (Lipofectin brand; Bethesda Research Labs, Gaithersburg, MD) | |
| CAT RNA: From Example 5 | |
| All formulations made up in DEPC-treated RNase-free water (International Biotechnologies, Inc., New Haven, CT 06535). | |

EXAMPLE 8: mRNA VACCINATION OF MICE TO PRODUCE THE gp120 PROTEIN OF HIV VIRUS

A liposomal formulation containing mRNA coding for the gp120 protein of the HIV virus is prepared according to Examples 1 through 5, except that the gene for gp120 (pHenv3-1 from the Aids Research and Reagent Program, National Institute of Allergy and Infectious Disease, Rockville, MD 20852) is inserted into the plasmid pXBG in the procedure of Example 4. A volume of 200 μ l of a formulation, prepared according to Example 6, and containing 200 μ g/ml of gp120 mRNA and 500 μ g/ml 1:1 DOTAP/PE in 10% sucrose is injected into the tail vein of mice 3 times in one day. At about 12 to 14 h after the last injection, a segment of muscle is removed from the injection site, and prepared as a cell lysate according to Example 7. The HIV specific protein gp120 is identified in the lysate also according to the procedures of Example 7.

The ability of gp120 antibody present in serum of the mRNA vaccinated mice to protect against HIV infection is determined by a HT4-6C plaque reduction assay, as follows:

HT4-6C cells (CD4+ HeLa cells) are obtained from Dr. Bruce Chesebro, (Rocky Mountain National Lab, Montana) and grown in culture in RPMI media (BRL, Gaithersburg, MD). The group of cells is then divided into batches. Some of the batches are infected with HIV by adding approximately 10^5 to 10^6 infectious units of HIV to approximately 10^7 HT4-6C cells. Other batches are tested for the protective effect of gp120 immune serum against HIV infection by adding both the HIV and approximately 50 μ l of serum from a mouse vaccinated with gp120 mRNA. After 3 days of incubation, the cells of all batches are washed, fixed and stained with crystal violet, and the number of plaques counted. The protective effect of gp120 immune serum is determined as the reduction in the number of plaques in the batches of cells treated with both gp120 mRNA-vaccinated mouse serum and HIV compared to the number in batches treated with HIV alone.

EXAMPLE 9: mRNA VACCINATION OF HUMAN STEM CELL-BEARING SCID MICE WITH *NEF* mRNA FOLLOWED BY HIV CHALLENGE

Severe combined immunodeficient mice (SCID mice (Molecular Biology Institute, (MBI), La Jolla, CA 92037)) were reconstituted with adult human peripheral blood lymphocytes by injection into the peritoneal cavity according to the method of Mosier (Mosier et al., *Nature* 335:256 (1988)). Intraperitoneal injection of 400 to 4000 infectious units of HIV-1 was then performed. The mice were maintained in a P3 level animal containment facility in sealed glove boxes.

mRNA coding for the *nef* protein of HIV was prepared by obtaining the *nef* gene in the form of a plasmid (pGM92, from the NIAID, Rockville, MD 20852); removing the *nef* gene from the plasmid; inserting the *nef* gene in the pXBG plasmid for transcription; and purifying the transcription product *nef* mRNA as described in Examples 2 through 5. The *nef* mRNA was then incorporated into a formulation according to Example 6. 200 microliter tail vein injections of a 10% sucrose solution containing 200 μ g/ml *nef* RNA and 500 μ g/ml 1:1 DOTAP:DOPE (in RNA/liposome complex form) were performed daily on experimental animals, while control animals were likewise injected with RNA/liposome complexes containing 200 μ g/ml yeast tRNA and 500 μ g/ml 1:1 DOTAP/DOPE liposomes. At 2, 4 and 8 weeks post injection, biopsy specimens were obtained from injected lymphoid organs and prepared for immunohistochemistry. At the same time points, blood samples were obtained and assayed for p24 levels by means of an ELISA kit (Abbott Labs, Chicago, IL) and virus titer by the plaque assay of Example 8. Immunostaining for HIV-1 was performed as described (Namikawa et al., *Science* 242:1684 (1988)) using polyclonal serum from a HIV infected patient. Positive cells were counted and the number of infected cells per high power field (400x) were determined. Using these assays, at least a 2 fold reduction in the number of positive staining cells was observed at 8 weeks, and titer and p24 expression was reduced by at least 50%. Together, these results indicate a moderate anti-viral effect of the (*in vivo*) treatment.

A volume of 200 μ l of the formulation, containing 200 μ g/ml of *nef* mRNA, and 500 μ g/ml 1:1 DOTAP:DOPE in 10% sucrose is injected into the tail vein of the human stem cell-containing SCID mice 3 times in one day. Following immunization, the mice are challenged by infection with an effective dose of HIV virus. Samples of blood are periodically withdrawn from the tail vein and monitored for production of the characteristic HIV protein p24 by an ELISA kit assay (Abbott Labs, Chicago, IL).

EXAMPLE 10: A METHOD OF PROVIDING ADENOSINE DEAMINASE TO MICE BY *IN VIVO* mRNA TRANSFECTION

The full-length sequence for the cDNA of the human adenosine deaminase (ADA) gene is obtained from the 1,300 bp EcoR1-AccI fragment of clone ADA 211 (Adrian, G. et al. *Mol. Cell Biol.* 4:1712 (1984)). It is blunt-ended, ligated to BglII linkers and then digested with BglII. The modified fragment is inserted into the BglII site of pXBG. ADA mRNA is transcribed and purified according to Examples 2 through 5, and purified ADA mRNA is incorporated into a formulation according to Example 6. Balb 3T3 mice are injected directly in the tail vein with 200 μ l of this formulation, containing 200 μ g/ml of ADA mRNA, and 500 μ g/ml DOTAP in 10% sucrose.

The presence of human ADA in the tissues of the liver, skin, and muscle of the mice is confirmed by an isoelectric focusing (IEF) procedure. Tissue extracts were electrofocused between pH 4 and 5 on a non-denaturing gel. The gel was then stained for *in situ* ADA activity as reported by Valerio, D. et al. *Gene* 31:137-143 (1984).

A preliminary separation of human and non-human ADA is carried out by fast protein liquid chromatography (FPLC). The proteins are fractionated on a Pharmacia (Piscataway, NJ) MonoQ column (HR5/5) with a linear gradient from 0.05 to 0.5 M KCl, 20 mM Tris (pH 7.5). Activity for ADA within the fractions is measured by reacting the fractions with 14 C-adenosine (Amersham, Chicago, IL) which is converted to inosine. Thin layer chromatography (0.1 M NaPi pH 6.8 saturated ammonium sulfate:n-propylalcohol/100:60:2) is used to separate the radioactive inosine from the substrate adenosine.

EXAMPLE 11: *IN VIVO* EXPRESSION OF PURE RNA AND DNA INJECTED DIRECTLY INTO THE MUSCLES OF MICE

The quadriceps muscles of mice were injected with either 100 μ grams of pRSVCAT DNA plasmid or 100 μ grams of β gCAT β gA_n RNA and the muscle tissue at the injection site later tested for CAT activity.

Five to six week old female and male Balb/C mice were anesthetized by intraperitoneal injection with 0.3 ml of 2.5% Avertin. A 1.5 cm incision was made on the anterior thigh, and the quadriceps muscle was directly visualized. The DNA and RNA were injected in 0.1 ml of solution in a 1cc syringe through a 27 gauge needle over one minute, approximately 0.5 cm from the distal insertion site of the muscle into the knee and about 0.2 cm deep. A suture was placed over the injection site for future localization, and the skin was then closed with stainless steel clips.

3T3 mouse fibroblasts were also transfected *in vitro* with 20 μ g of DNA or RNA complexed with 60 μ g of Lipofectin™ (BRL) in 3 ml of Opti-Mem™ (Gibco), under optimal conditions described for these cells (Malone, R. et al. Proc. Nat'l. Acad. Sci. USA 86:6077-6081(1989)). The same fibroblasts were also transfected using calcium phosphate according to the procedure described in Ausubel et al. (Eds) Current Protocols in Molecular Biology, John Wiley and Sons, New York (1989).

The pRSVCAT DNA plasmid and β gCAT β gA_n RNA were prepared as described in the preceding examples. The RNA consisted of the chloramphenicol acetyl transferase (CAT) coding sequences flanked by 5' and 3' β -globin untranslated sequences and a 3' poly-A tract.

Muscle extracts were prepared by excising the entire quadriceps, mincing the muscle into a 1.5 ml microtube containing 200 μ l of a lysis solution (20 mM Tris, pH 7.4, 2 mM MgCl₂ and 0.1% Triton X), and grinding the muscle with a plastic pestle (Kontes) for one minute. In order to ensure complete disruption of the muscle cells, the muscle tissue was then placed under 41.4 kg/cm² (600 psi) of N₂ in a bomb (Parr) at 4°C for 15 min before releasing the pressure.

Fibroblasts were processed similarly after they were trypsinized off the plates, taken up into media with serum, washed 2X with PBS, and the final cell pellet suspended into 200 μ l of lysis solution. 75 μ l of the muscle and fibroblast extracts were assayed for CAT activity by incubating the reaction mixtures for 2 hours with C¹⁴-chloramphenicol, followed by extraction and thin-layer chromatography, all as described in Example 7.

Figure 1 comprises autoradiograms from two separate experiments showing CAT activity within extracts of the injected quadriceps muscles. Lane numbers appear at the top of the autoradiograms and the % chloramphenicol conversions are at the bottom. Sample locations are as follows:

| | |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Lanes 1 and 13: | Control fibroblasts |
| Lanes 2 and 14: | Muscle injected only with 5% sucrose |
| Lanes 3 and 15: | 0.005 units of non-injected, purified CAT standard |
| Lanes 4 and 16: | 0.05 units of purified CAT (Sigma) |
| Lanes 5 to 8: | Muscle injected with 100 μ g of β gCAT β gA _n RNA in 5% sucrose |
| Lanes 11, 12, and 17 to 20: | Muscle injected with 100 μ grams pRSVCAT DNA in 5% sucrose |
| Lanes 9 and 10: | 20 μ grams of β gCAT β gA _n RNA, lipofected, with 60 μ grams of DOTMA, into a 70% confluent 60 mm plate of 3T3 cells ($\sim 10^6$) |
| Lanes 21, 22: | 20 μ grams of pRSVCAT lipofected, with 60 μ g of DOTMA, into a 50% confluent 60 mm plate of 3T3 cells |
| Lanes 23, 24: | 20 μ g of pRSVCAT calcium phosphate lipofected into a 50% confluent 60 mm plate of 3T3 cells. |

CAT activity was readily detected in all four RNA injection sites 18 hours after injection and in all six DNA injection sites 48 hours after injection. Extracts from two of the four RNA injection sites (Figure 1, lanes 6 and 8) and from two of the six DNA injection sites (Figure 1, lanes 11 and 20) contained levels of CAT activity comparable to the levels of CAT activity obtained from fibroblasts transiently transfected *in vitro* under optimal conditions (Figure 1, lanes 9, 10, 21-24). The average total amount of CAT activity expressed in muscle was 960 pg for the RNA injections and 116 pg for the DNA injections. The variability in CAT activity recovered from different muscle sites probably represents variability inherent in the injection and extraction technique, since significant variability was observed when pure CAT protein or pRSVCAT-transfected fibroblasts were injected into the muscle sites and immediately excised for measurement of CAT activity. CAT activity was also recovered from abdominal muscle injected with the RNA or DNA CAT vectors, indicating that other muscle groups can take up and express polynucleotides.

EXAMPLE 12: SITE OF *IN VIVO* EXPRESSION OF PURE DNA INJECTED DIRECTLY INTO THE MUSCLES OF MICE

The site of gene expression in injected muscle was determined by utilizing the pRSVLac-Z DNA vector (P. Norton

and J. Coffin *Molec. Cell Biol.* 5:281-290 (1985)) expressing the *E. coli* β -galactosidase gene for injection and observing the *in situ* cytochemical staining of muscle cells for *E. coli* β -galactosidase activity. The quadriceps muscle of mice was exposed as described in the previous example. Quadriceps muscles were injected once with 100 μ g of pRSVLAC-Z DNA in 20% sucrose. Seven days later the individual quadriceps muscles were removed in their entirety and every fifth

15 μ m cross-section was histochemically stained for β -galactosidase activity.

The muscle biopsy was frozen in liquid N₂-cooled isopentane. 15 μ m serial sections were sliced using a cryostat and placed immediately on gelatinized slides. The slides were fixed in 1.5% glutaraldehyde in PBS for 10 minutes and stained 4 hours for β -galactosidase activity (J. Price et al. *Proc. Nat'l Acad. Sci. USA* 84:156-160 (1987)). The muscle was counterstained with eosin.

10 The photographed sections (Figure 2) are as follows:

(A): Cross-section of control muscle injected with a solution containing only 20% sucrose, 60X magnification.

(B) (C) and (D): Cross-sections of a muscle injected with pRSVLacZ at 25X, 160X, and 400X magnification, respectively.

15 (E): A longitudinal section of another muscle injected with pRSVLacZ, 160X.

(F) (G) and (H): Serial cross-sections of the same muscle that are 0.6 mm apart.

Approximately 60 muscle cells of the approximately 4000 cells (1.5%) that comprise the entire quadriceps and approximately 10-30% of the cells within the injection area were stained blue (Figures 2B, C, and D). Control muscle injected with only a 20% sucrose solution did not show any background staining (Figure 2A). Positive β -galactosidase staining within some individual muscle cells was at least 1.2 mm deep on serial cross-sections (Figures 2F, G, and H), which may be the result of either transfection into multiple nuclei or the ability of cytoplasmic proteins expressed from one nucleus to be distributed widely within the muscle cell. Longitudinal sectioning also revealed β -galactosidase staining within muscle cells for at least 400 μ m (Figure 2E). In cells adjacent to intensely blue cells, fainter blue staining often

25 appeared in their bordering areas. This most likely represents an artifact of the histochemical β -galactosidase stain in which the reacted X-gal product diffuses before precipitating.

Similar results are obtained with linear DNA.

EXAMPLE 13: DOSE-RESPONSE EFFECTS OF RNA AND DNA INJECTED INTO MUSCLES OF MICE

30 Experiments with the firefly luciferase reporter gene (LUC) explored the effect of parameters of dose level and time on the total luciferase extracted from injected muscle.

The RNA and DNA vectors were prepared, and the quadriceps muscles of mice injected as previously described. Muscle extracts of the entire quadriceps were prepared as described in Example 11, except that the lysis buffer was 100mM KPi pH 7.8, 1 mM DTT, and 0.1% Triton X. 87.5 μ l of the 200 μ l extract was analyzed for luciferase activity (J. de Wet et al. *Molec. Cell Biol.* 7:725-737(1987)) using an LKB 1251 luminometer. Light units were converted to picograms (pg) of luciferase using a standard curve established by measuring the light units produced by purified firefly luciferase (Analytical Luminescence Laboratory) within control muscle extract. The RNA and DNA preparations prior to injection did not contain any contaminating luciferase activity. Control muscle injected with 20% sucrose had no detectable luciferase activity. All the above experiments were done two to three times and specifically, the DNA time points

40 greater than 40 days were done three times.
The Figures 3 A to 3 C illustrate the results of the following:

3(A) Luciferase activity measured 18 hours following the injection of varying amounts of β gLuc β gA_n RNA in 20% sucrose and 4 days following the injection of varying amounts of pRSVL in 20% sucrose

3(B) Luciferase activity assayed at varying times after 20 μ g of β gLuc β gA_n RNA were lipofected into a million 3T3 fibroblasts (Malone, R. et al. *Proc. Nat'l Acad. Sci. USA* 86:6077-6081 (1989), and after 100 μ g of β γ Δ τ β gA_n RNA in 20% sucrose were injected into quadriceps.

3(C) Luciferase activity assayed at varying times after pRSVL DNA was injected intramuscularly.

50 A. Level of Gene Expression

A dose-response effect was observed when quadriceps muscles were injected with various amounts of β gLuc β gA_n RNA or DNA pRSVL constructs (Figure 3A). The injection of ten times more DNA resulted in luciferase activity increasing approximately ten-fold from 33 pg luciferase following the injection of 10 μ g of DNA to 320 pg luciferase following the injection of 100 μ g of DNA. The injection of ten times more RNA also yielded approximately ten times more luciferase. A million 3T3 mouse fibroblasts in a 60 mm dish were lipofected with 20 μ g of DNA or RNA complexed with 60 μ g of Lipofectin™ (Bethesda Research Labs) in 3 ml of Opti-MEM™ (Gibco). Two days later, the cells were assayed for

luciferase activity and the results from four separate plates were averaged. Twenty μg of pRSVL DNA transfected into fibroblasts yielded a total of 120 pg of luciferase (6 pg luciferase/ μg DNA), while 25 μg injected into muscle yielded an average of 116 pg of luciferase (4.6 pg luciferase/ μg DNA; Figure 3A). The expression from the RNA vectors was approximately seven-fold more efficient in transfected fibroblasts than in injected muscles. Twenty μg of $\beta\text{gLuc}\beta\text{gA}_n$ RNA transfected into fibroblasts yielded a total of 450 pg of luciferase, while 25 μg injected into muscle yielded 74 pg of luciferase (Figures 3A and 3B). Based on the amount of DNA delivered, the efficiency of expression from the DNA vectors was similar in both transfected fibroblasts and injected muscles.

B. Time Course of Expression

The time course was also investigated (Figures 3B and 3C). Luciferase activity was assayed at varying times after 25 μg of $\beta\text{gLuc}\beta\text{gA}_n$ RNA or 100 μg of pRSVL DNA were injected. Following RNA injection, the average luciferase activity reached a maximum of 74 pg at 18 hours, and then quickly decreased to 2 pg at 60 hours. In transfected fibroblasts, the luciferase activity was maximal at 8 hours. Following DNA injection into muscle, substantial amounts of luciferase were present for at least 60 days.

The data in Figure 3B suggest that luciferase protein and the *in vitro* RNA transcript have a half-life of less than 24 hours in muscle. Therefore, the persistence of luciferase activity for 60 days is not likely to be due to the stability of luciferase protein or the stability of the *in vivo* RNA transcript.

EXAMPLE 14: PERSISTENCE OF DNA IN MUSCLE FOLLOWING INJECTION AS DETERMINED BY SOUTHERN BLOT ANALYSIS

Preparations of muscle DNA were obtained from control, uninjected quadriceps or from quadriceps, 30 days after injection with 100 μg of pRSVL in 20% sucrose. Two entire quadriceps muscles from the same animal were pooled, minced into liquid N_2 and ground with a mortar and pestle. Total cellular DNA and HIRT supernatants were prepared (F.M. Ausubel et al. (Eds) Current Protocols in Molecular Biology, John Wiley, New York (1987)). Fifteen μg of the total cellular DNA or 10 μl out of the 100 μl of HIRT supernatant were digested, run on a 1.0% agarose gel, transferred to Nytran™ (Schleicher and Schuell, New York), using a vacublot apparatus (LKB) and hybridized with multiprimed ^{32}P -luciferase probe (the HindIII-BamHI fragment of pRSVL). Following hybridization overnight, the final wash of the membrane was with 0.2X SSC containing 0.5% SDS at 68°C. Kodak XAR5 film was exposed to the membrane for 45 hours at -70°C.

Figure 4 is an autoradiogram of a Southern blot having a sample pattern as follows:

| | |
|------------|-------------------------------------------------------------------------------------|
| Lane 1: | 0.05 ng of undigested pRSVL plasmid |
| Lane 2: | 0.05 ng of BamHI digested pRSVL |
| Lane 3: | Blank |
| Lane 4: | BamHI digest of HIRT supernatant from control muscle |
| Lane 5: | BamHI digest of cellular DNA from control, uninjected muscle |
| Lanes 6,7: | BamHI digest of HIRT supernatant from two different pools of pRSVL injected muscles |
| Lanes 8,9: | BamHI digest of cellular DNA from two different pools of pRSVL injected muscle |
| Lane 10: | Cellular DNA (same as Lane 9) digested with BamHI and DpnI |
| Lane 11: | Cellular DNA (Same as in Lane 9) digested with BamHI and MboI |
| Lane 12: | Cellular DNA digested with BglII |
| Lane 13: | HIRT supernatant digested with BglII |

(Size markers (λ /HindIII) are shown at the left).

Southern blot analysis of muscle DNA indicates that the foreign pRSVL DNA is present within the muscle tissue for at least 30 days (Figure 4, lanes 6-9) and is similar to the levels of DNA present in muscle two and 15 days following injection. In muscle DNA digested with BamHI (which cuts pRSVL once; Figure 4, lanes 6-9), the presence of a 5.6 kb band that corresponds to linearized pRSVL (Figure 4, lane 2) suggest that the DNA is present either in a circular, extrachromosomal form or in large tandem repeats of the plasmid integrated into chromosome. In muscle DNA digested with BglII (which does not cut pRSVL), the presence of a band smaller than 10 kb (Figure 4, lanes 12 and 13) and at the same size as the open, circular form of the plasmid pRSVL (Figure 4, lane 1) implies that the DNA is present extrachromosomally in an open, circular form. The appearance of the pRSVL DNA in HIRT supernatants (Figure 4, lanes 6, 7, and 13) and in bacteria rendered ampicillin-resistant following transformation with HIRT supernatants also suggest that the DNA is present unintegrated. Although the majority of the exogenous DNA appears to be extrachromosomal, low levels of chromosomal integration cannot be definitively excluded. Overexposure of the blots did not reveal smears of hybridizing DNA larger than the 10 kb that would represent plasmid DNA integrated at random sites. The sensitivity of

the pRSVL DNA in muscle to DPNI digestion (Figure 4, lane 10) and its resistance to MboI digestion (Figure 4, lane 11), suggests that the DNA has not replicated within the muscle cells.

EXAMPLE 15: *IN VIVO* EXPRESSION OF PURE DNA IMPLANTED DIRECTLY INTO THE MUSCLE OF MICE

pRSVL DNA was precipitated in ethanol and dried. The pellet was picked up with fine forceps and deposited into various muscle groups as described in the preceding examples. Five days later the muscle was analyzed for luciferase activity as described in Example 13. The DNA was efficiently expressed in different muscle groups as follows:

| Implant: 25 µg pRSVL DNA | Luciferase Activity (Light Units, LU): | | | |
|--------------------------|----------------------------------------|--------|--------|------------|
| | Control | Biceps | Calf | Quadriceps |
| | 428 | 46420 | 27577 | 159080 |
| | 453 | 53585 | 34291 | 35512 |
| | | 1171 | 106865 | |
| | | 53397 | 105176 | |
| | | 499 | 40481 | |

EXAMPLE 16: DIRECT GENE DELIVERY INTO LUNG: INTRATRACHEAL INJECTION OF DNA, DNA/CL COMPLEXES OR PURE PROTEIN

The DNA luciferase vector (pRSVL), complexed with Lipofectin™, was injected intratracheally into rats either in 20% sucrose (2 rats) or in 5% sucrose (6 rats). Two days following the injection, the rat lungs were divided into 7 sections: LUL, LLL, RUL, RML, RLL, AL, (defined as follows) and Trachea. The rat lung differs from that of the human in having one large left lung off the left main bronchus. The left lung for this study was cut in half into a left upper part (LUL) and left lower part (LLL). The right lung contains 4 lobes: right cranial lobe (RUL), right middle lobe (RML), right lower lobe (RLL), and an accessory lobe (AL). Extracts were prepared by mincing these lung parts into separate 1.5 ml microtubes containing 200 µl of a lysis solution (20 mM Tris, pH 7.4, 2 mM MgCl₂ and 0.1% Triton X), and grinding the lung with a plastic pestle. (Kontes) for one minute. In order to ensure complete disruption of the lung cells, the lung tissue was then placed under 41.4 kg/cm² (600 psi) of N₂ in a Parr bomb at 4°C for 15 minutes before releasing the pressure. Luciferase assays were done on 87.5 µl of lung extract out of a total volume of about 350 µl.

| Injection | RUL | RLL | LUL | LML | LLL | AL | Trachea |
|------------------------|-------|------|-------------|-------------|-------------|------|---------|
| Mock | 22.6 | 22.4 | 21.9 | 21.3 | 20.1 | 19.8 | - |
| 25 µg DNA alone | 21.2 | 21.5 | 21.8 | 21.6 | 21.9 | 21.2 | - |
| 25 µg DNA alone | 21.7 | 21.4 | 21.3 | - | 22.2 | 21.5 | - |
| 250 µg DNA alone | 21.7 | 23.2 | 21.9 | 28.5 | 22.6 | 22.0 | 21.3 |
| 250 µg DNA alone | 22.9 | 22.5 | 33.3 | 23.0 | 25.4 | 24.3 | 21.5 |
| 250 µg DNA alone | 21.8 | 21.5 | 21.8 | 20.4 | 20.7 | 20.8 | 20.7 |
| 25 µg DNA/CL | 20.8 | 22.2 | 19.6 | 22.3 | 22.3 | 22.0 | - |
| 25 µg DNA/CL | 22.9 | 22.0 | 22.7 | 21.7 | 22.8 | - | 22.18 |
| 25 µg DNA/CL | 22.2 | 23.8 | 22.1 | 23.9 | 22.8 | - | 21.6 |
| 25 µg DNA/CL | 20.9 | 20.9 | 20.9 | 20.6 | 20.3 | - | 19.3 |
| 25 µg DNA/CL | 19.8 | 20.0 | 20.3 | 20.2 | 20.1 | 20.3 | 20.1 |
| 25 µg DNA/CL | 20.5 | 20.5 | 19.8 | 19.5 | 19.9 | 19.9 | 19.8 |
| Luc Protein | | | | | | | |
| 3x10 ⁴ I.u. | 105.3 | 77.1 | 98.7 | 80.0 | 86.3 | 89.6 | 178.9 |
| Blank | 22.5 | | | | | | |

Mock: Values are those for an animal that received 25 µg of DNA in 0.3 ml 20% sucrose into the esophagus. (A sample containing only water yields 22.5 I.u.)
 25 µg DNA alone: represent separate animals that received intratracheal injections of 25 µg of pPGKLuc in 0.3 ml 20% sucrose.
 25 µg DNA/CL: represent separate animals that received intratracheal injections of 25 Mg of pPGKLuc complexed with Lipofectin™ in 0.3 ml 5% sucrose.
 The above animals were sacrificed and lung extracts prepared 2 days after injection.
 Luc Protein 10⁴ I.u.: represents an animal that received the equivalent of 30,000 light units (I.u.) of purified firefly luciferase (Sigma), and then was immediately sacrificed.

The luciferase activity in the 25 µg DNA alone and the 25 µg DNA/CL groups of animals were not greater than that in the mock animal; however, in the 250 µg DNA alone animals, three lung sections showed small but reliably elevated I.u. activity above control lung or blanks (Bold, underlined). Duplicate assays on the same extract confirmed the result. Experience with the LKB 1251 luminometer indicates that these values, although just above background, indicate real luciferase activity.

EXAMPLE 17: LUCIFERASE ACTIVITY IN MOUSE LIVER DIRECTLY INJECTED WITH DNA FORMULATIONS

The DNA luciferase expression vector pPGKLuc was injected intrahepatically (IH) into the lower part of the left liver lobe in mice. The pPGKLuc DNA was either injected by itself (450 Mg DNA in 1.0 ml 20% sucrose) or complexed with Lipofectin™ (50 µg DNA + 150 µg Lipofectin™ in 1.0 ml 5% sucrose). Three days following injection, the left liver lobe was divided into two sections (a lower part where the lobe was injected and an upper part of the lobe distant from the injection site) and assayed for luciferase activity as described in the preceding examples.

| Mice Intrahepatic Liver Injection | Luciferase Activity (Light Units, LU) | |
|-----------------------------------|---------------------------------------|--------------------|
| | Lower | Upper |
| Blank (20.2 LU) | | |
| Control: 20% Sucrose Only | 20.8 | 23.8 |
| 50 µg pPGKLuc + Lipofectin | <u>35.4</u> | 23.1 |
| 50 µg pPGKLuc + Lipofectin | <u>38.1</u> | 21.4 |
| 50 µg pPGKLuc + Lipofectin | 22.1 | 22.7 |
| 450 µg pPGKLuc | <u>43.7</u> | <u>29.2</u> |
| 450 µg pPGKLuc | <u>78.8</u> | 21.7 |
| 450 µg pPGKLuc | 21.7 | 20.8 |

Two of the three animals that received the pure pPGKLuc injections and two of the three animals that received pPGKLuc + Lipofectin™ injections had luciferase activity significantly above background (bold, underlined). The lower part of the liver lobe, which was directly injected, had larger amounts of luciferase activity than the upper part, which was distant from the injection site. Similar results have been obtained using pRSVCAT DNA expression vector and CAT assays. Luciferase activity was not detected three days after similar preparations of pPGKLuc (+ and - Lipofectin™) were injected into the portal circulation of rats.

EXAMPLE 18: EXPRESSION OF GROWTH HORMONE GENE INJECTED INTO LIVER AND MUSCLE

Mice were injected with the pXGH5 (metallothionein promoter-growth hormone fusion gene)(Selden Richard et al., *Molec. Cell Biol.* 6:3173-3179 (1986)) in both liver and muscle. The mice were placed on 76 mM zinc sulfate water. Later the animals were bled and the serum analyzed for growth hormone using the Nichols GH Kit.

A. Two mice were injected with 20 µg of pXGH5 gene complexed with 60 µg/ml of Lipofectin in 5% sucrose. One ml of this solution was injected into the liver and the ventral and dorsal abdominal muscles were injected with 0.1 ml in 7 sites two times. Two days later, the animals were bled. The serum of one animal remained at background level, while that of the other contained 0.75 ng/ ml growth hormone.

B. Three mice were injected with 0.1 ml of 1 mg/ml of pXGH5 in 5% sucrose, 2x in the quadriceps, 1x in the hamstring muscle, 1x in pectoralis muscle, and 1x in trapezoid muscles on two separate days. The results were as follows:

| Animal No. | Growth Hormone (ng/ml): Day 1 | Day 2 |
|-----------------------|-------------------------------|-------|
| 1 | 0.6 | 0.6 |
| 2 | 0.8 | 1.0 |
| 3 | 0.95 | 0.8 |
| Background: 0.5 ng/ml | | |

EXAMPLE 19: ANTIBODY PRODUCTION IN MICE DIRECTLY INJECTED WITH A GENE FOR AN IMMUNIZING POLYPEPTIDE

Mice were injected with a quantity of 20 µg of a plasmid construct consisting of the gp-120 gene, driven by a cytomegalovirus (CMV) promoter. The DNA was injected into the quadriceps muscle of mice according to the methods described in Example 11. Mouse 5 (Figure 5A) was injected in the quadriceps muscle with 20 µg of plasmid DNA in isotonic sucrose. Mouse 2 (Figure 5B) was injected with sucrose solution alone. Blood samples were obtained prior to

the injection (Day 0) at the times indicated on Figure 5, up to more than 40 days post injection. The serum from each sample was serially diluted and assayed in a standard ELISA technique assay for the detection of antibody, using recombinant gp-120 protein made in yeast as the antigen. Both IgG and IgM antibodies were detected as indicated in Figure 5. The study indicates that the gene retains its signal sequence, and the protein is efficiently excreted from cells.

EXAMPLE 20: ANTIBODY PRODUCTION IN MICE INJECTED WITH CELLS TRANSFECTED WITH A GENE FOR AN IMMUNIZING POLYPEPTIDE

The cell line BALB/C C1.7 (TIB 80) was obtained from the American Type Tissue Culture Collection. These cells were transfected with the gp-120 gene construct described in Example 19. To 0.75 ml OptiMEM™ (Gibco. Inc.) were added 6.1 µg of DNA. The quantity of 30 µg of cationic liposomes (containing DOTMA and cholesterol in a 70:30 molar ratio) were added to another 0.75 ml OptiMEM™. The mixtures were combined and 1.5 ml of OptiMEM™ containing 20% (v/v) fetal bovine calf serum was added. This solution was poured into a 60 mm plastic petri dish containing 80% confluent cells (approximately one million total cells per plate). At 3.2 hours after lipofection, the cells were detached from the plate with trypsin and EDTA treatment, washed with OptiMEM™ and resuspended in 0.1 ml OptiMEM™ with 10% fetal calf serum. These cells were injected (IP) into mice. Mouse I2 (Figure 6A) was injected with the transfected cells. Mouse I1 (Figure 6A) received an identical number of untransfected cells. Blood samples were obtained prior to the injection (Day 0) and at the times indicated in Figure 6. The serum samples were processed as in the preceding example. Both IgG and IgM antibodies were detected as indicated in Figure 6.

EXAMPLE 21: USE OF UNCAPPED 5' SEQUENCES TO DIRECT TRANSLATION OF DNA TRANSFECTED INTO CELLS *IN VITRO*

Two different DNA templates were constructed, both of which code for the synthesis of RNA that express the *E. coli* β-galactosidase reporter gene. A Lac-Z gene that contains the Kozak consensus sequence was inserted in place of the luciferase coding sequences of the pβGLucβGA_n template to generate the pβGLacZβGA_n template. The pEMCLacZβGA_n template was made by replacing the 5' β-globin untranslated sequences of pβGLacZβGA_n with the 588 bp EcoRI/NcoI fragment from the encephalomyocarditis virus (EMCV) (pE5LVPO in Parks, G. et al., *J. Virology* 60:376-384 (1986)). These EMC 5' untranslated sequences had previously been shown to be able to initiate efficient translation *in vitro* in reticulocytes lysates. We demonstrated that these sequences can also direct efficient translation when transfected into fibroblasts in culture. The percentage of blue cells was slightly greater in cells transfected with the uncapped EMCLacZβGA_n RNA than in cells transfected with the capped pEMCLacZβGA_n RNA. Transfection with either uncapped or capped pEMCLacZβGA_n RNA yielded a greater number of positive β-galactosidase cells than transfection with capped βGLacZβGA_n RNA. It has recently been shown that this EMC 5' untranslated sequence, as a component of vaccinia-T7 polymerase vectors, can increase translation of an uncapped mRNA 4 to 7-fold (Elroy-Stein, O. et al., *Proc. Natl. Acad. Sci. USA* 86:6126-6130 (1989)). These EMC sequences thus have the ability to direct efficient translation from uncapped messengers.

EXAMPLE 22: T7 POLYMERASE TRANSCRIPTION IN TRANSFECTED CELL CULTURES

An SV40-T7 polymerase plasmid containing T7 polymerase protein expressed off the SV40 promotor (Dunn, J. et al., *Gene* 68: 259 (1988)) was co-lipofected with the pEMCLacZβGA_n template DNA into 3T3 fibroblasts in culture to demonstrate that T7 polymerase transcription can occur via plasmids. Two different SV40-T7 polymerase expression vectors were used:

- (a) pSV-G1-A: pAR3126-SV40 promotor driving expression of T7 polymerase protein which is directed to the cytoplasm.
- (b) pSVNU-G1-A: pAR3132-SV40 promotor driving expression of T7 polymerase protein which is directed to the cytoplasm. Each of these two plasmids were co-lipofected with pEMCLacZβGA_n at 1:3 and 3:1 ratios into a 60 mm plates of 3T3 cells. The number of blue β-galactosidase cells were counted and scored as indicated below.

| β -gal template | Ratio: template/polymerase vector | Co-Lipofectant: | |
|---------------------------|-----------------------------------|-----------------|------------|
| | | pSV-G1-A | pSVNU-G1-A |
| β GLacZ β GAn | 3:1 | 0 | 1 |
| | 1:3 | 0 | 1 |
| EMCLacZ β GAn | 3:1 | 74 | 70 |
| | 1:3 | 45 | 15 |

EXAMPLE 23: EXPRESSION OF LUCIFERASE IN BRAIN FOLLOWING DIRECTED INJECTION OF MESSENGER RNA

Two adult mice and one newborn mouse were injected with the β gLuc β gA_n mRNA containing the 5' cap and prepared according to Example 13. In the adult mice, injections were from a stock solution of mRNA at 3.6 μ g/ μ l in 20% sucrose; injection volumes were 5 μ l, 2 injections into each of the bilateral parietal cortex, 4 injections per mouse. Tissue was assayed at 18 hours post injection, according to Example 13 using 200 μ l of brain homogenate, disrupted in a Parr bomb, and 87.5 μ l was taken for assay.

The results are as follows:

| Treatment | Animal I.D. | Hemisphere: | |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|-------------|-------|
| | | Left | Right |
| Sham Injection | AMra | 649 | 629 |
| β gLuc β gA _n | AMrb | 1,734 | 1,911 |
| The newborn mouse was injected with 1 μ l β gLuc β gA _n (3.6 μ g/ μ l; 20% sucrose) into the bilateral forebrain and tissues were similarly processed and analyzed. | | | |
| Treatment | Animal I.D. | Hemisphere: | |
| | | Left | Right |
| β gLuc β gA _n | NRr | 1,569 | 963 |

EXAMPLE 24: FUNCTIONAL EXPRESSION OF DYSTROPHIN IN DYSTROPHIC MOUSE MUSCLE *IN VIVO*

A plasmid containing the dystrophin gene under control of the Rous Sarcoma virus promoter was prepared from the Xp21 plasmid containing the complete dystrophin coding region and the SV40 poly A segment, which was cloned by Kunkel and colleagues. (Brumeister M., Monaco AP, Gillard EF, van Ommen GJ, Affara NA, Ferguson-Smith MA, Kunkel LM, Leach H. A 10-megabase physical map of human Xp21, including the Duchenne muscular dystrophy gene. Genomics 1988 Apr 2 (3):189-202; Hoffman, EP and Kunkel, LM Dystrophin abnormalities of Duchenne's/Becker Muscular Dystrophy. Neuron Vol. 2, 1019-1029 (1989); Koenig M., Monaco AP, Kunkel LM. The complete sequence of dystrophin predicts a rod-shaped cytoskeletal protein. Cell 1988 Apr 22, 53 (2):219-26) 200 μ g of the plasmid in 100 μ l of phosphate buffered saline was injected into the quadriceps of the mutant mouse strain lacking the dystrophin gene product (MDX mouse; Jackson labs). Expression of functional dystrophin was monitored 7 days post injection by immuno-histochemistry according to the procedures described by Watkins et al. and using the same anti-dystrophin antibody (anti-60 kd antibody with a fluorescent secondary antibody) obtained from Kunkel. Functional expression of the dystrophin gene product in the dystrophic mice was detected by comparing the pattern of fluorescence observed in cross-sections of quadriceps muscle from injected animals, with the fluorescence pattern observed in normal animals. (Watkins S.C., Hoffman E.P., Slayter H.S., Kunkel L.M., Immunoelectron microscopic localization of dystrophin in myofibers. Nature 1988, Jun 30; 333 (6176:863-6)). Normal dystrophin expression is localized underneath the plasma membrane of the muscle fiber, so that a cross section of the quadriceps muscle gives a fluorescence pattern encircling the cell. In addition dystrophin expression was quantitated by Western blot analysis using the affinity purified anti-60kd anti-

body.

EXAMPLE 25: ADMINISTRATION OF THE CORRECTING DYSTROPHIN GENE DIRECTLY INTO THE MUSCLE OF PATIENTS WITH DUCHENNE'S MUSCULAR DYSTROPHY.

5

Patients with muscular dystrophy are given multiple 200 ug injections of plasmid containing the functional dystrophin gene (see previous example) in 100 ul of phosphate buffered saline. While under light anesthesia the patients are injected at 5 cm intervals into the entire skeletal muscle mass directly through the skin without surgery. Patient recovery is evaluated by monitoring twitch tension and maximum voluntary contraction. In addition, biopsies of 300-500 muscle cells from an injected area are taken for histological examination, observing muscle structure and biochemical analysis of the presence of dystrophin, which is absent in patients with Duchenne's muscular dystrophy. Respiratory muscles, including the intercostal muscles which move the rib cage and the diaphragm, are particularly important impaired muscle groups in patients with muscular dystrophy. The intercostals can be reached by injection through the skin as can the other skeletal muscle groups. The diaphragm can be accessed by a surgical procedure to expose the muscle to direct injection of plasmid DNA.

15

There will be various modifications, improvements, and applications of the disclosed invention that will be apparent to those of skill in the art, and the present application is intended to cover such embodiments.

Claims

20

1. Use of a naked polynucleotide, defined as being free from association with transfection-facilitating viral particles, liposomal formulations, charged lipids, and precipitating agents, and further defined as being non-integrating into genomes of said cells, with the proviso that the naked polynucleotide is not an infectious viral polynucleotide, or an antisense polynucleotide and is not in association with transfection facilitating proteins; in the preparation of a medicament; said naked polynucleotide when introduced in vivo directly into tissue of said vertebrate operatively encodes a gene product that is therapeutic or immunogenic when produced as an expression product in cells of said vertebrate and that exerts a desired therapeutic or immunogenic effect in vivo.
2. Use according to Claim 1, wherein said expression product is a polypeptide.
3. Use according to Claim 2, wherein said gene product is immunogenic when produced as an expression product in cells of said vertebrate, and wherein the production of said expression product results in the induction of an immune response.
4. Use according to Claim 3, wherein said polypeptide is a Class I major histocompatibility antigen.
5. Use according to Claim 3, wherein said induction of said immune response serves to vaccinate said vertebrate against viral infection or chronic pathogen infection.
6. Use according to Claim 3, wherein said immune response is ameliorative.
7. Use according to Claim 3, wherein said immune response is protective.
8. Use according to Claim 3, wherein said immune response is humoral comprising the synthesis of antibody.
9. Use according to Claim 3, wherein said immune response is cellular comprising the production of cytotoxic T cells.
10. Use according to Claim 9, wherein said expression product is presented within the context of Class I major histocompatibility antigens.
11. Use according to Claim 2, wherein said gene product is therapeutic when produced as an expression product in cells of said vertebrate, and wherein the production of said expression product results in treatment of a disease.
12. Use according to Claim 11, wherein said polypeptide is interleukin-2 and said disease is cancer.
13. Use according to Claim 11, wherein said polypeptide is dystrophin and said disease is muscular dystrophy.
14. Use according to Claim 2 wherein said polynucleotide is non-replicating in cells of said vertebrate.

55

15. Use according to Claim 2, wherein said polynucleotide is a mRNA.
16. Use according to Claim 2, wherein said polynucleotide is a DNA.
- 5 17. Use according to Claim 16, wherein said DNA is operably linked to a promoter incorporated into a plasmid.
18. Use according to Claim 1, wherein said polynucleotide is a DNA, said expression product is an antisense RNA, and the production of said expression product results in treatment of a disease.
- 10 19. Use according to Claim 1, wherein said tissue is muscle.
20. Use according to Claim 19, wherein said muscle is skeletal muscle.
21. Use according to Claim 1, wherein said tissue is heart.
- 15 22. Use according to Claim 1, wherein said tissue is blood.
23. Use according to Claim 1, wherein said tissue is skin.
- 20 24. Use according to Claim 1, wherein said introduction comprises injecting said naked polynucleotide into said tissue.
25. Use according to Claim 24, wherein said injection comprises impressing said naked polynucleotide through the skin.
- 25 26. Use according to Claim 24, wherein said injection comprises inoculating said naked polynucleotide through a needle.
27. Use according to Claim 1, wherein said vertebrate is a mammal or a bird.
- 30 28. Use according to Claim 27, wherein said mammal is a human.
29. Use according to Claim 1, wherein said gene product is therapeutic or immunogenic when produced as an expression product in cells of said tissue, and whereby said expression product is produced in said cells.
- 35 30. Use according to Claim 1, wherein said introduction comprises delivering said naked polynucleotide into the interstitial space of said tissue.
31. Use according to Claim 1, wherein said naked polynucleotide is free from any delivery vehicle that can act to facilitate entry into cells in vivo.
- 40 32. A naked polynucleotide, defined as being free from association with transfection-facilitating viral particles, liposomal formulations, charged lipids, and precipitating agents, and further defined as being non-integrating into genomes of said cells; with the proviso that the naked polynucleotide is not an infectious viral polynucleotide, or an antisense polynucleotide and is not in association with transfection facilitating proteins; which operatively encodes a gene product that is therapeutic or immunogenic when produced as an expression product and that exerts a desired therapeutic or immunogenic effect after introduction into vertebrate tissue in vivo, for use as a medicament in vivo.

Patentansprüche

- 50 1. Verwendung eines nackten Polynukleotids, das als frei von einer Assoziation mit transfektionserleichternden viralen Teilchen, liposomalen Formulierungen, geladenen Lipiden und Fällungsmitteln definiert ist, und das weiterhin als nicht integrierend in Genome der besagten Zellen definiert ist, unter der Voraussetzung, dass das nackte Polynukleotid kein infektiöses virales Polynukleotid noch ein Gegensinn-Polynukleotid ist und nicht in Assoziation mit
- 55 transfektionserleichternden Proteinen ist, zur Herstellung eines Medikaments, wobei das besagte nackte Polynukleotid, wenn es in das Gewebe des besagten Wirbeltiers in vivo direkt eingeführt wird, operativ ein Genprodukt kodiert, das therapeutisch oder immunogen ist, wenn es als Expressionsprodukt in Zellen des besagten Wirbeltiers erzeugt wird und das den gewünschten therapeutischen und immunogenen Effekt in vivo zeigt.

2. Verwendung nach Anspruch 1, wobei das Expressionsprodukt ein Polypeptid ist.
3. Verwendung nach Anspruch 2, wobei das besagte Genprodukt immunogen ist, wenn es als ein Expressionsprodukt in Zellen des besagten Wirbeltieres erzeugt wird, und wobei die Produktion des besagten Expressionsprodukts zu einer Induktion einer Immunreaktion führt.
4. Verwendung nach Anspruch 3, wobei das besagte Polypeptid ein Haupthistokompatibilitätsantigen der Klasse I ist.
5. Verwendung nach Anspruch 3, wobei die besagte Induktion der besagten Immunreaktion zum Impfen des besagten Wirbeltieres gegen virale Infektion oder chronische pathogene Infektion dient.
6. Verwendung nach Anspruch 3, wobei die besagte Immunreaktion ameliorativ ist.
7. Verwendung nach Anspruch 3, wobei die Immunreaktion protektiv ist.
8. Verwendung nach Anspruch 3, wobei die besagte Immunreaktion eine humorale ist, welche die Synthese eines Antikörpers umfaßt.
9. Verwendung nach Anspruch 3, wobei die besagte Immunreaktion eine zelluläre ist, welche die Produktion von cytotoxischen T-Zellen umfaßt.
10. Verwendung nach Anspruch 9, wobei das besagte Expressionsprodukt in dem Kontext eines Haupthistokompatibilitätsantigens der Klasse I dargestellt wird.
11. Verwendung nach Anspruch 2, wobei das besagte Genprodukt therapeutisch ist, wenn es als ein Expressionsprodukt in Zellen des besagten Wirbeltieres produziert wird, und wobei die Produktion des besagten Expressionsprodukts zur Behandlung einer Krankheit führt.
12. Verwendung nach Anspruch 11, wobei das besagte Polypeptid Interleukin-2 und die besagte Krankheit Krebs ist.
13. Verwendung nach Anspruch 11, wobei das besagte Polypeptid Dystrophin und die besagte Krankheit Muskeldystrophie ist.
14. Verwendung nach Anspruch 2, wobei das besagte Polynukleotid in Zellen des besagten Wirbeltieres nicht replizierend ist.
15. Verwendung nach Anspruch 2, wobei das Polynukleotid eine mRNA ist.
16. Verwendung nach Anspruch 2, wobei das besagte Nukleotid eine DNA ist.
17. Verwendung nach Anspruch 16, wobei die besagte DNA an einen Promotor, der einem Plasmid einverleibt ist, wirksam gebunden ist.
18. Verwendung nach Anspruch 1, wobei das Polynukleotid eine DNA ist, das Expressionsprodukt eine GegenmRNA ist und die Produktion des besagten Expressionsprodukts zur Behandlung einer Krankheit führt.
19. Verwendung nach Anspruch 1, wobei das besagte Gewebe ein Muskel ist.
20. Verwendung nach Anspruch 19, wobei der besagte Muskel ein Skelettmuskel ist.
21. Verwendung nach Anspruch 1, wobei das besagte Gewebe Herz ist.
22. Verwendung nach Anspruch 1, wobei das besagte Gewebe Blut ist.
23. Verwendung nach Anspruch 1, wobei das besagte Gewebe Haut ist.
24. Verwendung nach Anspruch 1, wobei die besagte Einführung die Injektion des besagten nackten Polynukleotids in das besagte Gewebe umfaßt.

25. Verwendung nach Anspruch 24, wobei die besagte Injektion das Einpressen des nackten Nukleotids durch die Haut umfaßt.

26. Verwendung nach Anspruch 24, wobei die besagte Injektion die Inokulation des besagten Polynukleotids durch eine Nadel umfaßt.

27. Verwendung nach Anspruch 1, wobei das Wirbeltier ein Säugetier oder ein Vogel ist.

28. Verwendung nach Anspruch 27, wobei das Säugetier ein Mensch ist.

29. Verwendung nach Anspruch 1, wobei das besagte Genprodukt therapeutisch oder immunogen ist, wenn es als Expressionsprodukt in Zellen des besagten Gewebes produziert wird, und wobei das Expressionsprodukt in den besagten Zellen produziert wird.

30. Verwendung nach Anspruch 1, wobei die Einführung die Zufuhr des besagten nackten Polynukleotids in den interstitiellen Raum des besagten Gewebes umfaßt.

31. Verwendung nach Anspruch 1, wobei das besagte nackte Polynukleotid frei von irgendeinem Zufuhrvehikel ist, das den Eintritt in Zellen in vivo erleichtern kann.

32. Ein nacktes Polynukleotid, das als frei von einer Assoziation mit transfektionserleichternden viralen Teilchen, liposomalen Formulierungen, geladenen Lipiden und Fällungsmitteln definiert ist, und das weiterhin als nicht integrierend in Genome der besagten Zellen definiert ist, unter der Voraussetzung, dass das nackte Polynukleotid kein infektiöses virales Polynukleotid noch ein Gegensinn-Polynukleotid ist und nicht in Assoziation mit transfektionserleichternden Proteinen ist, welches operativ ein Genprodukt kodiert, das therapeutisch und immunogen ist, wenn es als Expressionsprodukt erzeugt wird, und das einen gewünschten therapeutischen und immunogenen Effekt nach der Einführung in ein Wirbeltiergewebe in vivo zeigt, zur Verwendung als Medikament in vivo.

Revendications

1. Utilisation d'un polynucléotide nu, défini comme n'étant pas associé à des particules virales facilitant la transfection, à des formulations liposomales, à des lipides chargés et à des agents précipitants, et défini en outre comme n'étant pas intégré dans des génomes desdites cellules à condition que le polynucléotide nu ne soit pas un polynucléotide viral infectieux, ou un polynucléotide antisens et ne soit pas associé à des protéines facilitant la transfection; dans la préparation d'un médicament; ledit polynucléotide nu, lorsqu'il est introduit directement in vivo dans les tissus dudit vertébré, code de manière opérationnelle un produit génique qui est thérapeutique ou immunogène lorsqu'il est produit comme produit d'expression dans les cellules dudit vertébré et qui exerce in vivo un effet thérapeutique ou immunogène recherché.

2. Utilisation selon la revendication 1, dans laquelle ledit produit d'expression est un polypeptide.

3. Utilisation selon la revendication 2, dans laquelle ledit produit génétique est immunogène lorsqu'il est produit comme un produit d'expression dans les cellules dudit vertébré, et dans laquelle la production dudit produit d'expression a pour résultat l'induction d'une réponse immunitaire.

4. Utilisation selon la revendication 3, dans laquelle ledit polypeptide est un antigène majeur d'histocompatibilité de classe I.

5. Utilisation selon la revendication 3, dans laquelle ladite induction de ladite réponse immunitaire sert à vacciner ledit vertébré contre une infection virale ou une infection pathogène chronique.

6. Utilisation selon la revendication 3, dans laquelle ladite réponse immunitaire est amélioratrice.

7. Utilisation selon la revendication 3, dans laquelle ladite réponse immunitaire est protectrice.

8. Utilisation selon la revendication 3, dans laquelle ladite réponse immunitaire est humorale, comprenant la synthèse d'un anticorps.

9. Utilisation selon la revendication 3, dans laquelle ladite réponse immunitaire est cellulaire comprenant la production de cellules T cytotoxiques
- 5 10. Utilisation selon la revendication 9, dans laquelle ledit produit d'expression est présenté dans le contexte des antigènes majeurs d'histocompatibilité de classe I.
11. Utilisation selon la revendication 2, dans laquelle ledit produit génique est thérapeutique lorsqu'il est produit comme un produit d'expression dans les cellules dudit vertébré, et dans laquelle la production dudit produit d'expression a pour résultat le traitement d'une maladie.
- 10 12. Utilisation selon la revendication 11, dans laquelle ledit polypeptide est l'interleukine 2 et ladite maladie est un cancer.
13. Utilisation selon la revendication 11, dans laquelle ledit polypeptide est la dystrophine et ladite maladie est une dystrophie musculaire.
- 15 14. Utilisation selon la revendication 2, dans laquelle ledit polynucléotide ne se réplique pas dans les cellules dudit vertébré.
- 20 15. Utilisation selon la revendication 2, dans laquelle ledit polynucléotide est un ARNm.
16. Utilisation selon la revendication 2, dans laquelle ledit polynucléotide est un ADN.
- 25 17. Utilisation selon la revendication 16, dans laquelle ledit ADN est lié de manière opérationnelle à un promoteur incorporé dans un plasmide.
18. Utilisation selon la revendication 1, dans laquelle ledit polynucléotide est un ADN, ledit produit d'expression est un ARN antisens, et la production dudit produit d'expression a pour résultat le traitement d'une maladie.
- 30 19. Utilisation selon la revendication 1, dans laquelle ledit tissu est un muscle.
20. Utilisation selon la revendication 19, dans laquelle ledit muscle est un muscle squelettique.
21. Utilisation selon la revendication 1, dans laquelle ledit tissu est le coeur.
- 35 22. Utilisation selon la revendication 1, dans laquelle ledit tissu est le sang.
23. Utilisation selon la revendication 1, dans laquelle ledit tissu est la peau.
- 40 24. Utilisation selon la revendication 1, dans laquelle ladite introduction comprend l'injection dudit polynucléotide nu dans ledit tissu.
25. Utilisation selon la revendication 24, dans laquelle ladite injection comprend la pénétration dudit polynucléotide nu à travers la peau.
- 45 26. Utilisation selon la revendication 24, dans laquelle ladite injection comprend l'inoculation dudit polynucléotide nu à travers une aiguille.
27. Utilisation selon la revendication 1, dans laquelle ledit vertébré est un mammifère ou un oiseau.
- 50 28. Utilisation selon la revendication 27, dans laquelle ledit mammifère est un humain.
29. Utilisation selon la revendication 1, dans laquelle ledit produit génique est thérapeutique ou immunogène lorsqu'il est produit comme produit d'expression dans les cellules dudit tissu, et par laquelle ledit produit d'expression est produit dans lesdites cellules.
- 55 30. Utilisation selon la revendication 1, dans laquelle ladite introduction comprend la libération dudit polynucléotide nu dans l'espace interstitiel dudit tissu.

31. Utilisation selon la revendication 1, dans laquelle ledit polynucléotide nu est exempt de tout véhicule de libération pouvant agir pour faciliter l'entrée dans les cellules in vivo.

5 32. Polynucléotide nu, défini comme n'étant pas associé à des particules virales facilitant la transfection, à des formulations liposomales, à des lipides chargés, et à des agents précipitants et défini en outre comme ne s'intégrant pas dans le génome desdites cellules; à condition que le polynucléotide nu ne soit pas un polynucléotide viral infectieux, ou un polynucléotide antisens et ne soit pas associé à des protéines facilitant la transfection; qui code de manière opérationnelle un produit génique qui est thérapeutique ou immunogène lorsqu'il est produit comme produit d'expression et qui exerce un effet thérapeutique ou immunogène recherché après introduction dans des tissus
10 de vertébrés in vivo, pour une utilisation comme médicament in vivo.
